*In memory of Giyoo Hatano
for his enormous contribution
to the study of culture and psychology*

About the Editors

Shinobu Kitayama, PhD, is Professor of Psychology and Director of the Culture and Cognition Program at the University of Michigan. He received his doctorate from the University of Michigan, where he has been teaching since 2003. Prior to joining the faculty there, Dr. Kitayama taught at the Universities of Oregon and Chicago and at Kyoto University. He serves as an Associate Editor of the *Personality and Social Psychology Bulletin*. Throughout his career Dr. Kitayama has studied cultural variations of self, emotion, and cognition and has presented his work in the books *Emotion and Culture: Empirical Studies of Mutual Influences* (with Hazel Markus) and *The Heart's Eye: Emotional Influences in Perception and Attention* (with Paula Niedenthal), as well as in such leading journals as *Psychological Review*, *Psychological Science*, and the *Journal of Personality and Social Psychology*.

Dov Cohen, PhD, received his doctorate from the University of Michigan and taught at the University of Waterloo, Ontario, Canada, and the University of Illinois, where he is currently a faculty member. His research interests relate to cultural continuity and change, within-culture variability, and the way people position themselves with respect to dominant cultural ideals. Dr. Cohen has conducted research on the cultural syndromes of honor, dignity, and face, as well as on cross-cultural similarities and differences in the experience of self. He coauthored the book *Culture of Honor* (with Richard Nisbett) and coedited *Culture and Social Behavior* (with Richard Sorrentino, James Olson, and Mark Zanna).

Preface

Although it has many important predecessors in related disciplines such as anthropology, linguistics, and sociology, the field of cultural psychology as we know it today has only recently become a major force in the discipline of psychology. In its initial stage, during the 1980s, the field received a substantial boost from Richard Shweder's admonition, "Culture and psyche make each other up." By this, he meant that culture is not a "thing" out there; rather, it is a loosely organized set of interpersonal and institutional processes driven by people who participate in those processes. By the same token, the psyche is also not a discrete entity packed in the brain. Rather, it is a structure of psychological processes that are shaped by and thus closely attuned to the culture that surrounds them. Accordingly, culture cannot be understood without a deep understanding of the minds of people who make it up and, likewise, the mind cannot be understood without reference to the sociocultural environment to which it is adapted and attuned. In significant ways, the field has since evolved by exploring the nature of the mutual constitution of culture and the psyche.

Because many of us who engaged in this exploration were committed empirical psychologists, substantial effort was devoted to the questions of how culture might foster and even create different forms of psychological processes and how one could identify demonstrable consequences of such cross-culturally divergent psychological processes. These questions were raised and addressed with respect to some central topics of psychology, including self, identity, cognition, emotion, motivation, and interpersonal relationships.

Sometimes, initial efforts were guided by a rather simple heuristic of finding out specific ways in which the contemporary theories in psychology might be seen as culturally bound, and were largely confined to middle-class, young, Western samples. In retrospect, this might seem reactive, because it searched for limitations and problems with "mainstream psychology." Curiously, however, the empirical effort designed to show limitations of "mainstream theories" did in fact have more positive, proactive consequences. It enabled the researchers to extend existent theories, elaborate on them, and thus refine them as full-fledged theories of the interactions between sociocultural processes and psychological processes. In large part because of this, we believe that the field of cultural psychology has emerged from the periphery of the discipline to establish itself as a mainstay of contemporary psychology. Culture, then, has become an indispensable way to en-

rich basic theories of psychology. Here the current cultural approach in psychology differs most significantly from its cousins both in the past and the present.

This handbook represents an overview of the field of cultural psychology as it exists today. It starts with historical and disciplinary backgrounds of the field (Part I, “The Discipline and Its History”), followed by discussions of some theoretical perspectives and methodological advances (Part II, “Theory and Methods”). The main body of the handbook comprises more than 20 reviews of the diverse areas the field encompasses. The major themes include “Identity and Social Relations” (Part III), “Acquisition and Change of Culture” (Part IV), “Cognition” (Part V), and “Emotion and Motivation” (Part VI). We have compiled a total of 36 chapters, written by more than 60 top-notch researchers who pursue a diverse array of questions about culture.

We are very happy and proud of what has come out as a major reference volume for the field. We believe that one virtue of any endeavor of this magnitude is to encourage our colleagues and new generations of researchers to reflect on our current shortcomings and drawbacks, which in reality constitute a fertile source of ideas, visions, and empirical hypotheses for further expansions and elaborations of the field. The best contribution this handbook makes, then, may be to provide a moment of such critical self-appraisals. If it can meet this modest aspiration, we may also hope that it will be remembered as a noteworthy stepping stone by succeeding generations of researchers on culture and the human mind.

Contents

I. THE DISCIPLINE AND ITS HISTORY

1. Sociocultural Psychology: The Dynamic Interdependence among Self Systems and Social Systems 3
Hazel Rose Markus and MarYam G. Hamedani
2. Anthropological Foundations of Cultural Psychology 40
Robert A. LeVine
3. Culture and Psychology: A History of the Study of Their Relationship 59
Harry C. Triandis
4. Evolutionary Foundations of Cultural Psychology 77
Melvin Konner

II. THEORY AND METHODS

5. Cultural–Historical Activity Theory: Integrating Phylogeny, Cultural History, and Ontogenesis in Cultural Psychology 109
Michael Cole and Giyoo Hatano
6. Self as Cultural Mode of Being 136
Shinobu Kitayama, Sean Duffy, and Yukiko Uchida
7. Integrating System Approaches to Culture and Personality: The Cultural Cognitive–Affective Processing System 175
Rodolfo Mendoza-Denton and Walter Mischel

8. Methods in Cultural Psychology 196
Dov Cohen
9. Cultural Neuroscience: Parsing Universality and Diversity
across Levels of Analysis 237
Joan Y. Chiao and Nalini Ambady
10. Priming “Culture”: Culture as Situated Cognition 255
Daphna Oyserman and Spike Wing-Sing Lee

III. IDENTITY AND SOCIAL RELATIONS

11. Social Relationships in Our Species and Cultures 283
Alan P. Fiske and Susan T. Fiske
12. Culture and Social Identity 307
Marilynn B. Brewer and Masaki Yuki
13. Multicultural Identities 323
Ying-yi Hong, Ching Wan, Sun No, and Chi-yue Chiu
14. Cultural Psychology of Workways 346
Jeffrey Sanchez-Burks and Fiona Lee
15. Culture and Social Structure: The Relevance of Social Structure
to Cultural Psychology 370
Carmi Schooler

IV. ACQUISITION AND CHANGE OF CULTURE

16. Food and Eating 391
Paul Rozin
17. Religion’s Social and Cognitive Landscape: An Evolutionary Perspective 417
Scott Atran
18. Cultural Evolution and the Shaping of Cultural Diversity 454
Lesley Newson, Peter J. Richerson, and Robert Boyd
19. Cultural Psychology of Moral Development 477
Joan G. Miller

20. Situating the Child in Context: Attachment Relationships and Self-Regulation in Different Cultures 500
Gilda A. Morelli and Fred Rothbaum
21. Biocultural Co-Construction of Developmental Plasticity across the Lifespan 528
Shu-Chen Li

V. COGNITION

22. Intelligence and Culture 547
Robert J. Sternberg
23. Perception and Cognition 569
Ara Norenzayan, Incheol Choi, and Kaiping Peng
24. Narrative Reverberations: How Participation in Narrative Practices Co-Creates Persons and Cultures 595
Peggy J. Miller, Heidi Fung, and Michele Koven
25. Culture, Categorization, and Reasoning 615
Douglas L. Medin, Sara J. Unsworth, and Lawrence Hirschfeld
26. Culture and Memory 645
Qi Wang and Michael Ross
27. Language, Cognition, and Culture: Beyond the Whorfian Hypothesis 668
Chi-yue Chiu, Angela K-y. Leung, and Letty Kwan

VI. EMOTION AND MOTIVATION

28. Culture and Subjective Well-Being 691
William Tov and Ed Diener
29. Culture and Motivation: What Motivates People to Act in the Ways That They Do? 714
Steven J. Heine
30. The Cultural Psychology of Emotion 734
Batja Mesquita and Janxin Leu
31. Passionate Love and Sexual Desire 760
Elaine Hatfield, Richard L. Rapson, and Lise D. Martel

32. Emotion, Biology, and Culture 780
Robert W. Levenson, José Soto, and Nnamdi Pole
33. Culture and Psychopathology: Foundations, Issues, and Directions 797
Anthony J. Marsella and Ann Marie Yamada

VII. COMMENTARIES FROM TWO PERSPECTIVES

34. An Anthropological Perspective: The Revival of Cultural Psychology—
Some Premonitions and Reflections 821
Richard A. Shweder
35. A Psychological Perspective: Cultural Psychology—Past, Present, and Future 837
Richard E. Nisbett

VIII. EPILOGUE

36. Cultural Psychology: This Stanza and the Next 847
Dov Cohen and Shinobu Kitayama

- Subject Index 873

PART I

THE DISCIPLINE
AND ITS HISTORY

CHAPTER 1

Sociocultural Psychology

The Dynamic Interdependence among Self Systems and Social Systems

HAZEL ROSE MARKUS
MARYAM G. HAMEDANI

The word *cultural* has modified psychology throughout its history. Cole (1990) calls cultural psychology “a once and future discipline,” Shweder (1990, 2003) notes that cultural psychology’s time has arrived “once again,” and J. G. Miller (1999) contends that psychology is and “always has been cultural.” Despite important and often heated arguments about differences among the areas designated by the terms “cultural psychology,” “cross-cultural psychology,” “sociocultural psychology,” “psychological anthropology,” and “situated cognition” (Atran, Medin, & Ross, 2005; Berry, 2000; Keller et al., 2006; Keller & Greenfield, 2000; Kim & Berry, 1993; Markus & Kitayama, 1991; Matsumoto, 2001; Nisbett, 2003; Norenzayan & Heine, 2005; Shweder & Sullivan, 1990, 1993; Triandis, 1989; Veroff & Goldberger, 1995; Vygotsky, 1978; Wertsch, 1991), the joint reemergence of these terms and the robust interest they have generated is a significant developmental marker for the field of psychology. The theory

and research produced under these flags reveal a new and mature appreciation for an old and powerful idea. Expressed in a wide variety of ways, the core of this historically elusive and empirically challenging notion is that people and their social worlds are inseparable: They require each other.

The psychological—typically defined as patterns of thought, feeling, and action, sometimes also called the mind, the psyche, the self, agency, mentalities, ways of being, or modes of operating—is grounded in and also fosters the sociocultural. The sociocultural—or patterns in the social world, sometimes called socialities, sociocultural contexts, social systems, the environment, social structure, or culture—is grounded in and fosters the psychological. Thus, in a process of ongoing *mutual constitution*, the psychological and the cultural “make each other up” (Shweder, 1990, p. 24), and are most productively analyzed and understood together (Adams & Markus, 2001; Kashima, 2000; Wertsch & Sammarco, 1985).

The history of what we label here as “sociocultural psychology” is a story characterized by both a persistent attraction to the idea that culture and psyche make each other up, and an equally strong resistance to this idea, set up by the pervasive individualist representation—particularly densely distributed in North American contexts—that “it’s what’s inside” the person and not the “context” that matters the most. The current wave of rapidly expanding interest among social scientists regarding how behavior is socially and culturally constituted is driven, we suggest, by a confluence of several factors: (1) a robust set of empirical findings that challenge many of psychology’s signature theories, and are thus not easily interpreted with dominant or mainstream frameworks; (2) a growing realization among psychologists that the capacity for culture making and culture sharing is at the core of what it means to be human, and that this capacity is a clear evolutionary advantage of the human species (Bruner, 1990; Carrithers, 1992; Kashima, 2000; Mesquita, 2003; Schaller & Crandall, 2004; Tomasello, 1999); and (3) an increasing sophistication in how to conceptualize both the cultural and the psychological, such that the nature of their mutual and reciprocal influence can be examined.

We have organized our review and integration of the sociocultural perspective in psychology around a set of questions:

1. Mutual constitution—what does it mean?
2. A sociocultural approach—what is it?
3. A sociocultural approach—where does it come from?
4. What does a sociocultural approach add to psychology?
5. What definition of culture is suitable for psychology?
6. Assessing mutual constitution—what are the current approaches?
7. Sociocultural psychology—what next?

MUTUAL CONSTITUTION—WHAT DOES IT MEAN?

Sociocultural psychologists begin their theorizing with the person and several key observations. People exist everywhere in social networks, in groups, in communities, and in relationships. They are chronically sensitive and attuned to the thoughts, feelings, and ac-

tions of others. Their actions (i.e., their ways of being an agent in the world, their identities, their *selves*) require, reflect, foster, and institutionalize these sociocultural affordances and influences. Thus, as people actively construct their worlds, they are made up of, or “constituted by,” relations with other people and by the ideas, practices, products, and institutions that are prevalent in their social contexts (i.e., environments, fields, situations, settings, worlds). The people whose thoughts, feelings, and actions are included in this circuit of mutual constitution include the individuals’ contemporaries, the individual him or herself, and many others who have gone before and left their respective worlds replete with representations, products, and systems reflecting prior thoughts, feelings, and actions.

The major focus of the last two decades of research in sociocultural psychology has been to discover just how mutual constitution proceeds. What does it mean about the brain, the mind, and behavior to say that they are cultural or socioculturally constituted? For some researchers, the goal has been to show that ideas, practices, and products are not separate from “experience” or applied *after* behavior. The sociocultural is not “overlaid” on a set of *basic* or *fixed* psychological processes. Instead, ideas, practices, and products are active and incorporated in the very formation and operation of psychological processes (e.g., Cole, 1996; Markus, Mullally, & Kitayama, 1997; J. G. Miller, 1994; Nisbett, 2003; Wertsch, 1991). The goal of other researchers has been to show that the context is not separate or external to the person but is, in fact, the psychological externalized or materialized (D’Andrade & Strauss, 1992; Kitayama, Markus, Matsumoto, & Norasakkunkit, 1997; Markus, Uchida, Omoregie, Townsend, & Kitayama, 2005; Shore, 1996). In the terms of Shweder (1995), who has pioneered the theoretical development of modern cultural psychology, the goal is to find ways to talk about the psychological and about the cultural such that neither “is by nature intrinsic or extrinsic to the other” (p. 69).

Our intent in this chapter’s title is to signal our focus on theories and research that examine the structure and patterning inherent in various social worlds, how this patterning continually shapes psychological functioning, and how people (*selves* or *agents*) require and depend on these patterns as they become

meaning-*full* participants in their social worlds. The patterning of social worlds includes ideas and images, as well as the embodiment, animation, and realization of these ideas and images in social practices, material products, and institutions (here called “social systems”).

We use the word *sociocultural* rather than the term *cultural* to emphasize that a sociocultural analysis includes within its scope both the conceptual and the material. Thus, it includes both *meanings*—ideas, images, representations, attitudes, values, prototypes, and stereotypes—and what is often termed the *sociostructural*—cultural products, interpersonal interactions, institutional practices and systems—and person–situation contingencies, all of which embody, as well as render material and operable, normative patterns prevalent in a given context. We invoke the term *interdependence* to convey the sense that as people are involved in the processes of mutual constitution, they are not passive recipients of culture. Instead they are active agents who are socioculturally shaped *shapers* of themselves and their worlds. The causal arrows between social and psychological formation are bidirectional; the constitution is mutual.

Finally, we use the term *dynamic* to signal that sociocultural patterns of ideas, practices, and products are not fixed, but are open and complex networks or distributions of mental and material resources that are often, although not always, linked with significant, in the sense of psychologically meaningful (socially, politically, historically), constructed categories such as ethnicity, race, religion, gender, occupation, political party, social class, caste, sect, tribe, or region of the country or world. These categories are elements of the repertoire of symbolic resources that people themselves invoke, or that are invoked by others, to render the social world meaningful. Such sets of ideas, practices, products, and institutions are constantly in flux and undergoing transformation as they are engaged—appropriated, incorporated, contested—by selves acting or being in the world. Others’ ways of categorizing the sociocultural context that are less well-instituted in existing contexts and map less well onto existing social categories (e.g., high or low gross domestic product [GDP] nations, red or blue America, mountainous or flat habitats) are also important to investigate.

A SOCIOCULTURAL APPROACH—WHAT IS IT?

The emerging sociocultural psychology reflects the most recent and most specific realization within psychology of the theory that being a person is fundamentally a social transaction (Asch, 1952; Baldwin, 1911; Lewin, 1948; Mead, 1934; for a review, see Cross & Markus, 1999). Moreover, it is an effort to extend and to elaborate empirically the view that social formations and psychological formations are fully interdependent, both contemporaneously and historically (Berger & Luckmann, 1966; Bourdieu, 1990; Moscovici, 1988; Shweder, 1990; Wundt, 1916).

From a sociocultural perspective, individuals are biological entities (as well as genetic, neuronal, chemical, hormonal entities), and all behavior has a biological, as well as an evolutionary, foundation. Yet individuals are also ineluctably social and cultural phenomena. The option of being *asocial* or *acultural*, that is, living as a neutral being who is not bound to particular practices and socioculturally structured ways of behaving, is not available. People eat, sleep, work, and relate to one another in culture-specific ways. As the rapidly expanding volume of theoretical and empirical studies has made clear, people also think and feel and act in culture-specific ways—ways that are shaped by the particular meanings and practices of their lived experiences (for reviews see Cole, 1996; Fiske, Kitayama, Markus, & Nisbett, 1998; Greenfield & Cocking, 1994; Heine, Lehman, Markus, & Kitayama, 1999; J. G. Miller, 1997; Nisbett & Cohen, 1996; Shweder, 1990, 2003; Shweder & LeVine, 1984; Smith & Bond, 1993). Becoming a mature, competent adult necessitates that an individual successfully engage the systems of meanings, practices, and institutions that configure the contexts of her particular everyday life (Bruner, 1990; Geertz, 1975; Markus et al., 1997; Shweder, 1982, 1990).

The sociocultural engagement that is an essential and constant process of human life is an *active* process that transforms the biological being into a social individual—a person with a self and a set of context-contingent identities. In the process of this cultural engagement, “others”—their language; their ideas of what is good, true, and real; their understandings of why and how to attend to, engage with, and operate within various worlds—become part of

a dynamic self that mediates and regulates behavior. The patterns and processes of individuals' social contexts condition their behavior and give form to the interpretive systems that organize the behavioral system. As people participate in their respective contexts, settings, and environments, they are constantly in the process of making meaning and reflecting these meanings in their actions by building them into products and practices in their worlds (Bruner, 1990; Hallowell, 1955; Markus & Kitayama, 1994; Shweder, 1990).

As Shweder (1990) postulates, the intentional person, or psyche, is interdependent with the intentional world, or culture. Intentional worlds are worlds of meanings—human artifactual worlds, populated with products of our own design. An intentional world, Shweder says, is replete with events such as “stealing” or “taking communion”; processes such as “harm” or “sin”; stations such as “in-law” or “exorcist”; practices such as “betrothal” or “divorce”; visible entities such as “weeds” and invisible entities such as “natural rights” (p. 42). These cultural products are not just expressions, correlates, or residue of behavior. Human behavior is premised on and organized by these taken-for-granted meanings and categorizations of social reality that are objectified in material objects and institutionalized in social relations and social systems.

For example, many urban, middle-class adults in North American contexts reveal high levels of self-esteem, self-efficacy, optimism, and intrinsic motivation; express a desire for mastery, control, and self-expression; and show preferences for uniqueness (Kim & Markus, 1999; Snibbe & Markus, 2005). This robust set of psychological tendencies is not, however, an expression of universal human nature. The middle-class contexts of North America are replete with choices; with requirements for self-expression and feeling good about the self; and with opportunities for focusing on the self, mastering, and controlling one's environment, and constructing the self as the primary source of action.

What is readily apparent from a comparative approach is that North American psychological tendencies have in many significant ways been created, fostered, and maintained by widely distributed ideas—such as the importance of individual achievement—and have been reinforced and instituted by dense networks of everyday practices—such as compli-

menting and praising one another for individual performance by a frequent distribution of awards and honors in classrooms and workplaces, and by situations such as job applications and interviews that require people to focus on their good features and explain their life outcomes in terms of their own actions and decisions. These psychological tendencies and everyday practices further structure worlds through intentional products such as coffee mugs, bumper stickers, cars, medications, and cigarette advertisements that declare “You're the best,” or exhort people to “Be a star,” “Take control,” “Never follow,” and “Resist homogenization.” Such practices and products foster material and behavioral environments in which self-serving and self-interested actions are valued and normative. These cultural resources thereby condition characteristic ways of being and are themselves the result of previous conditioned responding.

As we analyze the process of sociocultural transformation, two facts become apparent: (1) Individuals are not separate from social contexts, and (2) social contexts do not exist apart from or outside of people. Instead, contexts are the products of human activity: They are repositories of previous psychological activity, and they afford psychological activity. As a consequence, social contexts do more than what psychology typically labels “influence.” Instead, they “constitute,” as in create, make up, or establish, these psychological tendencies. The mental processes and behavioral tendencies that are the subject of study in psychology, then, are not separate from, but are fundamentally realized through, cultural ideas and practices.

As researchers and theorists turn toward a sociocultural approach, they take seriously Bruner's (1990) claim that it is impossible to “construct a human psychology on the basis of the individual alone” (p. 12). Developing a sociocultural psychology requires spanning the divides created by the many familiar and foundational psychological binaries, that is, person–situation, individual–environment, culture–social structure, and self–society, that conceptualize people as separate from their “surrounding” contexts. Moreover, there is a need to bridge the many disciplinary barriers that separate sociology, anthropology, and history from psychology.

Given the theorized interdependence of mind and sociocultural context, the assumption of a sociocultural psychology is that the psychologi-

cal nature of human beings can vary with time and space (Shweder, 2003). Thus, two central goals of sociocultural psychology are to examine variation in modes of psychological functioning across sociocultural contexts, and to specify the varied cultural meanings and practices with which they are linked (Fiske et al., 1998; Graumann, 1986; Markus, Kitayama, & Heiman, 1996; Moscovici, 1981; Shweder, 1990, 2003; Wundt, 1916). The field, however, is often identified with (and criticized for) the search for differences in subjectivities, as well as with what Shweder (1990) calls the “rejection of psychic unity.” In conjunction with this goal, however, sociocultural psychology seeks (1) to discover systematic principles underlying the diversity of culturally patterned socialities and psyches, and (2) to describe the processes by which all humans are constituted as fundamentally social beings.

Notably, the behavior of all individuals engaged in a particular (e.g., middle-class, European American) context is by no means uniform or identical, revealing that sociocultural contexts may constitute, in the sense of shape or condition, people in a variety of ways as they engage differently with their contexts. Contexts do not “determine,” in the sense of definitively settle or fix, the limits or forms of human behavior. People engage with and respond to the ideas and practices of a given context in somewhat variable ways, with variable intents and purposes. These varieties of engagement depend on the person’s own particular set of orienting, mediating, and interpretive frameworks, which themselves are the result of a host of other individual and situational differences, and also shape a person’s mode of being in the world. People, then, are never monocultural, because they are always interacting with multiple contexts (e.g., those delineated by gender, ethnicity, socioeconomic status, region, sexual orientation, occupation). Cultural contexts are therefore not monolithic: Various combinations of cultural ideas and practices intersect within individuals, so that individuals may have different reactions to the same context. Furthermore, as psychological tendencies are realized and expressed, they not only foster and reinforce but also sometimes change the contexts in which they are grounded. The consequences of cultural engagement on behavior, although systematic and predictable in many aspects, are never monolithic and invariable.

A SOCIOCULTURAL APPROACH— WHERE DOES IT COME FROM?

The major ideas of a sociocultural perspective, as we have sketched it here, have multiple overlapping sources throughout the social sciences and philosophy. They can be traced to Herder and to Vico in philosophy (Shweder, 2003; Taylor, 1997; see also Triandis, Chapter 3, this volume); to Boas, Hallowell, Kroeber, and Kluckhohn in anthropology (see LeVine, Chapter 2, this volume); to sociology (Berger & Luckmann, 1966; Bourdieu, 1991; Moscovici, 1991, 1998); and to a variety of psychological theorists, such as Wundt, Mead, Baldwin, Sullivan, G. Kelly, Asch, Lewin, and Bruner, all of whom emphasized meaning and the role of intersubjectively shared understandings in creating and maintaining reality. In general, sociocultural psychologists can be identified by their appreciation for the interdependence of the individual with the social, the material, and the historical, and by their view of people as active meaning makers and world makers.

Thinking Beyond the Person

Common to many approaches classified as sociocultural psychology is a belief that the sources of mind and behavior cannot all be located within the brain, the head, or the body. The sources of mind and behavior are distributed, existing both internally in the mind and externally in the world. This commitment to the ways in which psychological processes are made up of, or made by, the social elements of one’s contexts is revealed in some of psychology’s earliest theorizing, although the term *cultural* was not explicitly invoked. Wundt believed that no thought, judgment, or evaluation could be methodologically isolated from its sociocultural base (Graumann, 1986). More explicitly, Lewin (1948) wrote:

The perception of social space and the experimental and conceptual investigation of the dynamics and laws of the processes in social space are of fundamental and theoretical and practical importance. . . . The social climate in which a child lives is for the child as important as the air it breathes. The group to which the child belongs is the ground on which he stands. (p. 82)

Similarly, Allport (1948) noted that:

the group to which the individual belongs is the

ground for his perceptions, his feelings, and his actions. Most psychologists are so preoccupied with the salient features of the individual's mental life that they are prone to forget it is the ground of the social group that gives to the individual his figured character. Just as the bed of a stream shapes the direction and flow of water, so does the group determine the current of an individual's life. The interdependence of the ground and the figured flow is inescapable, intimate, dynamic, but is also elusive. (p. vii)

Extending these ideas, Wertsch and Sammarco (1985) argue forcefully, like Bruner, that to explain the individual one must go beyond the individual. They invoke the words of Luria (1981):

In order to explain the highly complex forms of human consciousness, one must go beyond the human organism. One must seek the origins of conscious activity and "categorical" behavior not in the recesses of the human brain or in the depths of the spirit, but in the external conditions of life. Above all, this means that one must seek these origins in external processes of social life, in the social and transhistorical forms of human existence. (p. 25)

Meaning Making as Basic Process

Another defining element of the sociocultural approach is the idea that, whereas the world suggests itself and can attract and bind attention, the person is not simply a passive recipient of what the social world has to offer, but is instead an active, intentional agent. From a sociocultural-psychological perspective, an essential element of behavior is an *engagement*, or a coming together, an encounter, of a person making sense of a world replete with meanings, objects, and practices (Asch, 1952; Bruner, 1990; Geertz, 1973).

Most recently, in summarizing several decades of research, Bruner (1990; see also Markus, Kitayama, & Heiman, 1996), invoked these now century-old claims about the social and cultural nature of the mind, then extended them. He specified how cultural systems give form and direction to our lives. It is culture, he contends, that

shapes human life and the human mind, that gives meaning to action by situating its underlying intentional states in an interpretive system. It does this by imposing the patterns inherent in the culture's symbolic systems—its language and dis-

course modes, the forms of logical and narrative explication, and the patterns of mutually dependent communal life. (p. 34)

WHAT DOES A SOCIOCULTURAL APPROACH ADD TO PSYCHOLOGY?

In short, the social systems that the self systems engage derive from previous psychological activity and provide the resources and blueprints for meaning-making and action. The organizing theme of a sociocultural approach, and of this chapter, is that people and their social worlds are inseparable: They fundamentally require each other. A comprehensive social-psychological science requires mapping the range of ways that the social world can be made meaningful, and analysis of the processes by which this meaning making and world making occur (Bruner, 1990; Markus, Kitayama, & Heiman, 1996; Shweder, 1990, 2003). Just as neuroscientists scan the brain, seeking to produce a neural mapping of the mind, so must psychologists scan the sociocultural environment to generate a sociocultural mapping of the mind. Attaching a wide-angle lens to the current psychological camera so as to encompass more fully the sociocultural (as well as the historical) will allow researchers to identify the meaningful contexts that ground and organize the cognitive, emotional, and behavioral tendencies observed in psychological studies.

Analyzing intentional worlds simultaneously as both products and shapers of psychological activity is challenging. Many features of the social environment—schools, churches, theaters, marriage, as well as many other social objects, roles, practices, and relations generated in the process of mutual constitution—are understandable only in terms of their social settings and functions. As Asch (1952) noted, "A chair, a dollar bill, a joking relative are social things; the most exhaustive physical, chemical and biological analysis will fail to reveal this most essential property" (p. 178).

Meanings

One category of the context that is central to understanding how the sociocultural and psychological make each other up is what Bruner (1990) and Shweder (1990) call "meanings," or what Sperber (1985) and Moscovici (1981)

call “representations.” Meanings or representations are useful units of mutual constitution, because they refer to constructed entities that cannot be located solely in the head of the meaning maker or solely in the practices or products of world; they are always distributed across both. Once ideas and images or other symbolic resources are instituted in actions and in the world, they are simultaneously forms of social knowledge and social practices (Moscovici, 1981). For example, the meanings associated with phenomena such as person, self, group, family, sex, marriage, friendship, enemyship, society, mind, emotion, consciousness, time, the future, the past, life, luck, death, goodness, evil, and human nature provide the substratum of images and assumptions that are essential for understanding sociocultural contexts. Some of these meanings are created, distributed, and instituted in response to critical—perhaps universal—problems of ethnicity, maturity, hierarchy, autonomy, and morality. Others speak to particular concerns and are more historically contingent or locally selected and derived.

One important goal of sociocultural psychology is to analyze the complex of meanings that have been naturalized and taken for granted as basic human drives, needs, or psychological processes, but that may be quite context-specific. Until recently, most psychologists have been Europeans and North Americans who have analyzed middle-class European and North American college students. The dense and extensive set of representations that are foundational for and specific to this context (including representations of independence, individual responsibility, self-determination, self-esteem, control, freedom, equality, choice, work, ability, intelligence, motivation, success, influence, achievement, power, and happiness), which lend structure and coherence to behavior, have been largely invisible and have gone unmarked (Jost & Major, 2001; Markus & Kitayama, 1994; Quinn & Crocker, 1999). Identifying the vast system of meanings that affords agency in middle-class European and North American contexts underscores the possibility of marked differences in agency in other contexts.

Substantial differences in these meanings in terms of how they are conventionalized and publically expressed in the environment (e.g., what is self, what is the group, what is emotion, what is life–death), and in how they are

distributed, provide useful ways of distinguishing among cultural contexts. Often these meanings are linked to meanings of socially and historically significant categories such as ethnicity, region of the world, or religion. Sociocultural psychologists have begun to systematically extract divergent meanings from various contexts (those associated with region of the country or world, religion, ethnicity, race, gender, age, sexual preference, social class, and occupation). They have identified multiple meanings for concepts that are psychological staples—concepts of self and identity, cognition, emotion, motivation, morality, well-being, friendship, family, and group. They have identified such broad concepts as independence and interdependence that are evident in some form in almost every context, but that differ in their prevalence, dominance, or in how densely they are elaborated and distributed in a given context. They have identified concepts such as happiness, control, and choice that appear to organize middle-class American psyches and contexts but that are not particularly prevalent or salient in other contexts. They have also distinguished many more specific concepts that can be understood and identified but are not emphasized or foregrounded in the middle-class North American perspective that still provides the unmarked framework of reference for most work in psychology. These include concepts such as honor, shame, adjustment, face, compassion, serenity, enemyship, hierarchy, respect, deference, propriety, moderation, balance, silence, divinity, restraint, and relativism, as well as a growing set of concepts such as *amae* or *simpatia* that can be translated but do not have simple English counterparts. Many sociocultural studies produce findings that are surprising and that pose questions for common middle-class North American understandings. For example, in Japanese contexts, happiness includes sadness (Uchida, Norasakkunkit, & Kitayama, 2004); in West African contexts, enemies are part of everyday life (Adams, 2005); in Latin American contexts, work requires socializing (Sanchez-Burks & Mor Barak, 2004), and in Taiwanese contexts, feeling good is more likely to be identified with feeling calm and tranquil than with feeling energized or excited (Tsai, Knutson, & Fung, 2006). These different ideas about what is normative or of value imply worlds and psyches organized in different ways from middle-class North American ones.

Practices

Cultural contexts are identified and maintained by not only shared subjective elements but also particular ways of acting and interacting in the recurrent episodes of everyday life. Thus, another category of the sociocultural context that can be analyzed is practices. As with meanings, a focus on practices is an effort to move beyond the individual considered in isolation (Cole, 1995; Kitayama et al., 1997; P. J. Miller & Goodnow, 1995; Rogoff, 1991). An emphasis on practices bridges the divide between thinking and other parts of psychological activity typically called “doing” or “being.” Participation in routine activities, such as talking to a friend, going shopping, going to the bank, attending a meeting, parenting, or teaching, expresses in concrete form what a given context communicates about how to be a normatively appropriate person, as well as what is regarded as “good,” “right,” or “real.” Practices, therefore, are not neutral behavior, but rather are those that “reflect a social and moral order” (Miller & Goodnow, 1995, p. 10). Practices, or what Bruner (1990) calls “acts,” are behaviors that reflect intention or meaning. Practices, then, are not just behavior; they are *meaningful* acts that coordinate the actions of individuals with those of others and maintain the social context. A practice perspective has been used to analyze, for example, processes of self-esteem maintenance (Heine et al., 1999; Kitayama et al., 1997; P. J. Miller & Goodnow, 1995), sleeping arrangements/sleeping behaviors (Shweder, Balle-Jensen, & Goldstein, 1995), hiring decisions (D. Cohen & Nisbett, 1997), prayer and religious activity (A. B. Cohen, Malka, Rozin, & Chermas, 2006; J. L. Tsai, Miao, & Seppala, in press), talking (H. S. Kim, 2002), and health promotion (Markus, Curhan, & Ryff, 2006).

Products

Within psychology, Cole (1990) has focused on cultural contexts as defined by a continual flow of constructed activity. He describes the material flow of culture and stresses that humans enter a world that is transformed by “the accumulated artifacts of previous generations.” Culture, then, is history in the present. Cole, who traces his thinking to the writings of Vygotsky, Luria, and Leontiev, claims that the main function of the cultural artifact is to inte-

grate people with the world and with each other. Cultural products can be conceptualized as the psychological externalized, or as the social order objectified. As noted by Asch (1952), such products have powerful effects on action. For example, products such as an abacus, a magazine advertisement, a child’s book, a song, the iPod on which said song is played, and, perhaps most obviously, the Internet are simultaneously conceptual and material. They carry with them past interactions, and they mediate the present. These products reflect the ideas, images, understandings, and values of particular contexts, and are therefore a good source of these meanings. Simultaneously, as people engage with these products, they re-present and institutionalize these ideas and values. In the last few years, a growing number of psychologists have analyzed cultural products, including song lyrics, television commercials, television news coverage, children’s storybooks, Web advertisements, want ads, personals ads, newspaper articles and headlines, photographs, school and university mission statements, and social networking sites (Aaker & Williams, 1998; H. Kim & Markus, 1999; Plaut & Markus, 2005; Rothbaum, Weisz, & Snyder, 1982; Snibbe & Markus, 2005; J. Tsai, Knutson, & Fung, 2006).

The goal of a sociocultural analysis is to analyze more of what is called “the situation” or “the environment,” and to expand psychology’s understanding of the role of individual in maintaining the situations that influence them. A sociocultural approach adds to psychology a focus on the content and function of meanings, practices, and products. Such a focus succeeds in analyzing “more” of the situation, providing a wider, and at the same time, a more in-depth view.

WHAT IS A DEFINITION OF CULTURE SUITABLE FOR PSYCHOLOGY?

Most of the research we are categorizing under the rubric of sociocultural psychology has concentrated on the psychological, leaving the patterning or the distribution or the coherence of the *sociocultural* mostly unspecified, and the workings of the process of mutual constitution unelaborated. For example, early cultural psychology investigations by J. G. Miller (1984), Triandis (1989), and Markus and Kitayama (1991) revealed detailed representations and

normative practices associated with observed differences in psychological tendencies. Most subsequent references to these studies, however, report the cultural differences observed as those between types of people—"individualists" and "collectivists," or "independents" and "interdependents," or "Westerners" and "Easterners." This type of description locates the sources of the behavioral differences in some internal attributes or traits of the *individuals* rather than in some aspects of the cultural contexts, or in the *transaction* between the individual and the context.

Cultural Psychology as Stereotyping 101?

Although it is easier to say "East Asians" or "interdependents" than to say "people participating in the ideas and practices that are pervasive in East Asian cultural contexts," the labels, even if it is only a shorthand, repeatedly reinforce the sense that observed psychological tendencies (e.g., a prevalent tendency to be aware of the preferences and expectations of close others and to correctly anticipate these preferences) derive from some properties or *traits* of interdependence or collectivism rather than from persistent engagement in a world that is structured in specific ways, and that requires and fosters a particular type of attention to others.

One of the formidable stumbling blocks on the road to a systematic sociocultural psychology has been the failure to articulate a definition of "culture" or "the sociocultural" that fits the idea that the psychological and sociocultural are dynamically making each other up. Without specific definitions, most observers, laypersons, and social scientists alike have gravitated toward the simple and widely distributed idea of culture as a collection of traits that define particular groups or collections of people. The commonsense idea reflected here is that a group is like a big person, and that "culture" is the group's "personality" or "character."

In everyday discourse, people make statements such as "He has visited 34 cultures," suggesting that cultures are specified by geographical boundaries. Other seemingly commonsense statements include "Members of Chinese culture are family oriented," or "Members of Mexican culture are hierarchical." Such statements can easily imply the view that cultures are monolithic and can be under-

stood as discrete, categorical groups that are "internally homogeneous, externally distinctive objects" (Hermans & Kempen, 1998, p. 1113). As noted by Adams and Markus (2004), such statements also suggest that culture is an entity, or some defining cultural essence that groups "have." From this perspective, culture is often understood as something extra that "other" groups "have," and is less often used to make sense of ingroup behavior.

Culture as Patterns

Most recent scientific definitions of culture conceptualize it very differently, departing markedly from the idea of culture as a bundle of traits or as a stable set of beliefs or norms, and are less likely to be vulnerable to the stereotyping charge. Instead, *culture* is defined as patterns of representations, actions, and artifacts that are distributed or spread by social interaction. Under this definition, the conceptual location of culture shifts from the interior of a person to the often-implicit patterns that exist simultaneously in people and in the world with which they necessarily engage in the course of any behavior. For example, Atran et al. (2005), in a recent description of the cultural mind, defines *culture* as "causally distributed patterns of mental representations, their public expression, and the resultant behaviors in given ecological contexts" (p. 751).

Among the hundreds of definitions of culture (Kroeber & Kluckhohn, 1952), many theorists (Adams & Markus, 2004; Shweder, 2003) developing sociocultural theory have returned to the insights of Kroeber and Kluckhohn (1952):

Culture consists of explicit and implicit *patterns* of historically derived and selected ideas and their embodiment in institutions, practices, and artifacts; cultural patterns may, on one hand, be considered as products of action, and on the other as conditioning elements of further action. (as summarized by Adams & Markus, 2004, p. 341; emphasis in original).

Using this type of definition, the focus is not on studying culture as collections of people, but is instead on how psychological process may be implicitly and explicitly shaped by the worlds, contexts, or cultural systems that people inhabit. Culture, then, is not about groups of people—the Japanese, the Americans, the

whites, the Latinos; thus, it is not groups themselves that should be studied. Rather, the focus should be on the implicit and explicit patterns of meanings, practices, and artifacts distributed throughout the contexts in which people participate, and on how people are engaged, invoked, incorporated, contested or changed by agents to complete themselves and guide their behavior. These ideas, practices, and artifacts, although not a fixed or coherent set and not shared equally by all in a given context, create and maintain the social level of reality that lends coherence to behavior and renders actions meaningful within a given cultural context.

A recent program of research on cognitive dissonance in East Asian and European American contexts (Kitayama, Snibbe, Markus, & Suzuki, 2004) is an example of a “culture as patterns” approach. These studies, along with earlier ones by Heine and Lehman (1997), demonstrate that people in East Asian cultural contexts did not show dissonance when tested in the standard dissonance conditions. In these studies participants rank-ordered a set of compact discs (CDs) according to their own preferences. Later, they were offered a choice between the fifth- and sixth-ranked CDs. When asked to give a second ranking of the 10 CDs, North Americans, but not East Asians, showed a strong justification effect; that is, they rated the CD that they had chosen more highly than the unchosen CD. Demonstrating one such difference between people engaging in two different cultural contexts was not the end, however, but rather the beginning of this series of studies. The goal was to account for the observed difference in terms of different patterns of ideas and practices relevant to choice, and furthermore, to understand what meanings and functions choice had in the two cultural contexts. In a series of subsequent studies, the situation was manipulated such that North American and East Asian participants made either a “public” or “private” choice. In the public condition, respondents were asked to consider the preferences of others or were exposed to the schematic faces of others. In these conditions East Asians, but not North Americans, revealed a tendency to justify their choices.

A careful analysis of the patterns of meaning and practices relevant to choice in East Asian and North American contexts explains these sharp differences in behavior. For North Americans, prevalent models of agency suggest that choices should express individual preferences

and be free from influence by others. In contrast, in East Asian cultural contexts, choice—like many actions—is an interpersonal phenomenon, an expression of one’s public stance, and is subject to social evaluation and criticism. As a consequence of this very different culturally shared and practiced model of agency, making a choice in public renders people vulnerable to a loss of face, honor, or reputation.

Together these studies examining variation in patterns of attention to self and other in the two contexts show that when choices are public, where the scrutiny of others is possible, rather than private, people in East Asian cultural contexts are likely to justify their actions. Other studies varying the nature of the other invoked during the choice situation—a liked versus disliked other—revealed that participants in East Asian contexts were particularly sensitive to the interpersonal nature of the situation compared with those in European American contexts. An analysis of this type illuminates context differences in normative patterns of how to be a person, and when and how to reference others. Still other studies by researchers focusing on choice as a prototypical agentic act (Iyengar & DeVoe, 2003; Savani, Markus, & Snibbe, 2006; Stephens, Markus, & Townsend, 2006) show that because choice in North American contexts is a signature of authentic agency and functions as a powerful schema for organizing behavior, people organize their own behavior and that of others in terms of choices and make inferences about behavior in terms of choice. By focusing on the behavioral patterns affording choice and analyzing how choice is understood and practiced in the two contexts, these studies underscore that differences in behavior among North Americans and Japanese are neither a result of something they “have” nor a matter of divergent traits or attributes. Instead, these differences are a function of something they do, of differences in their actions that result from engaging different symbolic resources and social systems.

ASSESSING MUTUAL CONSTITUTION: WHAT ARE THE CURRENT APPROACHES?

How are psychologists empirically examining the dynamic interdependence between socio-cultural context and mind? One important issue to consider is how researchers conceptual-

ize the psychological system with which the sociocultural system is interacting. Psychologists have typically carved up the psychological space into cognition, emotion, and motivation, and it is the cognitive system that has been the most elaborated in recent decades (Wierzbicka, 1994). These psychological systems have typically been assumed to function similarly across all people, but the database of psychological research has been based “almost completely on findings from samples of less than 10–15% of the populations on the face of the earth” (Rozin, 2001, p. 13), such as North America, Western Europe, and other regions in the English-speaking world (see also Gergen & Davis, 1985; Sears, 1986). This reliance on such a limited sampling of the human population may have led psychologists to conceptualize the psychological system in a fashion more congruent with their sample and with the cultural contexts most familiar to them.

Psychologists studying the dynamic interdependence between mind and culture have confronted the following questions in their research approach:

1. What counts as the psychological?
2. What counts as the sociocultural?
3. What is the nature of the mutually constituting relationship linking the two together?

Whether or not the psychological system functions similarly across all humans has been a central issue for psychologists assuming a sociocultural approach. Some would argue that the psychological system is universal, that it is made up from the same basic bits in the same fundamental fashion—in terms of cognition, emotion, and motivation—across all sociocultural contexts. Others ask why the psychological system has been carved up in this particular way, and whether or not it should be conceptualized in the same manner across all social worlds in which people engage.

Wierzbicka (1994), for example, notes that typical categories of emotion used in most psychological research may “constitute cultural artifacts of Anglo culture reflected in, and continually reinforced by, the English language” (p. 135). Rozin (2001), for example, identifies food, religion, ritual, leisure, sports, music, drama, money, and work as the major domains of human social life, thus contending that “there is no doubt that food, work, and leisure are the three most time consuming waking activities of human beings, and are all deeply so-

cial” (p. 13). He asks why psychologists have not organized their study of the psychological with these, or other, particular bits.

Surveying current empirical work in the field of sociocultural psychology, five major approaches emerge from the literature, offering perspectives on how to capture the dynamic interdependence between the psychological and the sociocultural. These five approaches are outlined first in this section. They are not mutually exclusive, although researchers utilizing them often attempt to conceptualize and investigate empirically the psychological study of sociocultural constitution in different ways. What varies among them is how they theoretically conceptualize and empirically investigate the psychological, the sociocultural, and the constituting relationship between the two. For each approach, this review focuses on its previous or prototypical, rather than prospective, contributions.

Following this description of the five approaches, some of the proposed central mechanisms and mediating processes that fashion the relationship between the cultural and the psychological are discussed. Finally, at the end of this chapter, an important distinction emerging in cultural psychological research is highlighted: conceptualizing culture as a constituting process versus a method of social influence.

Figure 1.1 summarizes and organizes the perspectives articulated by the five approaches. The schematics associated with each approach represent graphically how each approach conceptualizes the link between the psychological and the sociocultural. Each schematic contains a *P*, which represents the various structures and processes of the psychological system, and an *SC*, which represents elements of the various sociocultural contexts with which the psychological system engages. The size of the *P*s relative to the *SC*s vary to indicate the relative emphasis placed on the psychological or the sociocultural in each approach’s theoretical and empirical work. In each schematic, the arrows represent how the sociocultural and the psychological are considered to interact with one another, and we reflect this by varying the direction of the arrows and whether they are solid or dashed. A solid arrow indicates that the relationship is relatively well specified, while a dashed arrow indicates that the relationship is relatively less well specified in each approach’s theoretical and empirical work. Three of the schematics include additional terms (*dimension*, *ecology*, and *situation*) be-

APPROACH	EMPIRICAL GOAL	MECHANISM OF CONSTITUTION	EXAMPLE
<p>Dimensional</p>	Specify the dimensions of culture that explain differences in attitudes, beliefs, values, and behaviors.	Worldviews, beliefs, values, attitudes translate the sociocultural into the psychological.	Horizontal-vertical relationships dimension
<p>Models</p>	Specify models that organize the links between the sociocultural and self systems.	Psychological tendencies, meanings, practices, and products reflect, foster, and sustain one another.	Influencing-adjusting models of agency
<p>Cognitive Toolkit</p>	Specify how cultural meanings and practices can influence basic cognitive tendencies.	Attention and perception are guided by cognitive tools or sets of interpretive tools.	Holistic-analytic cognition
<p>Ecocultural</p>	Specify how ecological and sociopolitical factors influence psychological adaptation to a context.	Cultural adaptation and transmission shape the development and display of basic human characteristics.	Variations in cognitive competence
<p>Dynamic Constructivist</p>	Specify the situational factors and boundary conditions that govern cultural influence.	Particular knowledge structures/implicit theories are activated by situational cues in a given situation.	Bicultural frame switching

cause they are focal concepts explicitly theorized in each perspective.

Five Major Approaches

*The Dimensional Approach:
A Focus on Quantifying Differences*

Several cross-cultural researchers (e.g., Hofstede, 1980, 1990; Leung, 1987; Schwartz, 1990; Triandis, 1989, 1990, 1995) explain the source of cultural psychological variation by identifying certain key dimensions along which cultural contexts may differ. They argue that, for culture to function as a useful explanatory variable, it should be conceptualized as a complex, multidimensional structure that can be evaluated along a set of particular dimensions. Cultural differences may reflect underlying basic value orientations, beliefs, and worldviews prevalent in a context; however, these differences can be best and most parsimoniously captured by identifying and describing cultures according to where they fall along a series of

dimensions. Thus, each context’s distribution of behavior patterns, norms, attitudes, and personality variables can be measured and compared (Triandis, 1989). Triandis (1996) terms this series of dimensions *cultural syndromes*, which are “dimensions of cultural variation that can be used as parameters of psychological theories” (p. 407), are composed of attitudes, beliefs, norms, roles, self-definitions, and values shared by members in a given cultural context and can be organized around a series of central themes. The effect of the sociocultural on the psychological is therefore assumed to be “defined” by where a specific combination of people engaging in that culture, on average, “score” along a series of dimensions, thereby creating a particular patterning or cultural profile (i.e., syndrome). The dimensional approach, therefore, attempts to capture the ways the sociocultural may constitute the psychological by organizing potential sources of difference along a series of dimensions.

Some examples of these dimensions are power distance, uncertainty avoidance,

masculinity–femininity, and individualism–collectivism (Hofstede, 1980); tightness, complexity, active–passive, honor, collectivism–individualism, and vertical–horizontal relationships (Triandis, 1989, 1990, 1995, 1996); and mastery, hierarchy, conservatism, affective autonomy, intellectual authority, egalitarian commitment, and harmony (Schwartz, 1990). An example of how these dimensions function is that although both Sweden and Germany are individualistic contexts, (or contexts privileging a notion of personhood as independent, autonomous, and personally motivated), Sweden is a horizontally individualistic context, emphasizing egalitarian social relations, while Germany is a vertically individualistic context, emphasizing a hierarchical conception of relations between people and groups (Triandis, 1995). Thus, Swedish and German contexts, and their corresponding constitution of the psychological, can be more accurately characterized by utilizing both dimensions, and potential cultural psychological effects can be more precisely understood.

In this approach, therefore, the cultural dimension is the way of capturing how the sociocultural and the psychological interact. The dimensional approach places emphasis upon providing a parsimonious organizing structure by which a wide array of cultural elements and their effects on the psychological can be measured and compared; thus, they can be understood as dimensions of constitution. These dimensions of constitution can thereby be systematically organized around a particular set of effects. Furthermore, this approach creates a common metric by which different contextual influences on the psychological may be compared along a discrete number of elements.

The dimensional approach, however, places little emphasis on the process by which the sociocultural and the psychological mutually constitute one another. It focuses on organizing the effects of the sociocultural on the psychological, but as of yet has little to say about *how* this relationship functions. For the most part, this approach has not focused on how psychological values and attitudes might be translated into social institutions, conventions, and habitual psychological tendencies. For this reason, the schematic for this approach (Figure 1.1) highlights that the dimensional perspective focuses on quantifying the ways in which *SC* may interact with *P*, without examining the constituting processes

themselves. Thus, *SC* is connected to *P* only through particular *dimensions*, and *SC* and *P* are not treated with equal emphasis. The dimensional approach thereby offers a method of conceptualizing what can be considered “meta-constitution,” or a method of organizing the effects of mutual constitution without focusing on constituting processes themselves. Furthermore, this approach has not yet attempted to address the dynamic, changing nature of culture and its interdependence with the psychological, and can appear to view this relationship as rather static.

*The Sociocultural Models Approach:
A Focus on the Interacting Self System
and Sociocultural System*

Sociocultural models can be defined as culturally derived and selected ideas (both implicit and explicit) and practices (both informal and formal) about what is real, true, beautiful, good, and right—and what is not—that are embodied, enacted, or instituted in a given context (Markus & Kitayama, 2004; Shweder, 2003). Thus, sociocultural models give form and direction to individual experience, for example, perception, cognition, emotion, motivation, action. For example, models of agency provide implicit guidelines for “how to be,” reflecting both descriptive and normative understandings of how and why people act (Kitayama & Uchida, 2005; Markus et al., 2005). Sociocultural models are dynamic, in that they both contribute to the *mutual* constitution of culture and mind, and remain mutable over time (Fiske et al., 1998). The concept of sociocultural models derives from cultural and cognitive anthropology, as well as sociocultural psychology (D’Andrade, 1990; Fiske et al., 1998; Holland & Quinn, 1987; Shore, 1996; Shweder, 1990; Shweder et al., 1998; Strauss, 1992).

Shared meaning is central to their existence, in that a sociocultural model can be described as an intersubjective cognitive schema (D’Andrade, 1990). Cultural schemas, furthermore, “are presupposed, taken for granted models of the world that are widely shared (though not to the exclusion of other alternative models) by the members of a society and that play an enormous role in their understanding of the world and their behavior in it” (Holland & Quinn, 1987, p. 4). Sociocultural models are frequently imperceptible to the minds

that engage them, because they are represented at the private, internal, mental level and function by providing blueprints for how to think, feel, and act—how to *be*—in the world.

Particularly important to the sociocultural models approach is that models not only exist in the minds of people participating in a particular context but also structure the worlds in which people live. Culture is understood as public and exists before individuals participate in it (J. G. Miller, 1999). Shore (1996) emphasizes the point that cultural models exist not only as “cognitive constructs ‘in the mind’ of members of a community” (p. 44) but also as public artifacts and institutions “in the world” (see Berger & Luckmann, 1966). Hence, cultural models are also represented at the public, external, social, material level. This approach thereby focuses on how culture exists both “in the head” and “in the world,” demonstrating that culture not only interacts with the psychological via the “heads” of people engaging in a particular context but also via the material worlds that people inhabit.

The existence of cultural models is dynamic and mutually constituted by person and environment, contingent upon and negotiated through “endless social exchanges” (Shore, 1996). The theory of social representations (Moscovici, 1981), deriving from sociology and social psychology, is another articulation of a sociocultural models approach, emphasizing that systems of values, ideas, practices, and products serve as orienting devices that allow people to successfully navigate their social worlds. Furthermore, social representations enable effective communication to take place among members existing in the same context through engagement with shared meanings (Moscovici, 1981).

The sociocultural models approach has been utilized to examine phenomena such as self systems (Heine et al., 1999; Markus & Kitayama, 1991; Markus et al., 1997), agency (Kitayama & Uchida, 2005; Markus & Kitayama, 2004; Markus et al., 2005; Snibbe & Markus, 2005), modes of being (Kitayama, Duffy, & Uchida, Chapter 6, this volume), emotion (Mesquita, 2003; J. L. Tsai, Chentsova-Dutton, Freire-Bebeau, & Przymus, 2002), motivation (H. Kim & Markus, 1999), cognitive and social development (Cole, 1985, 1992; Cole, Gay, Glick, & Sharp, 1971; Greenfield & Childs, 1977a, 1977b; Maynard & Greenfield, 2003; Moiser & Rogoff, 2003; Rogoff, 1991, 1995;

Wertsch, 1991), morality (J. D. Miller, Bersoff, & Harwood, 1990; Shweder, Much, Mahapatra, & Park, 1997), food and eating behavior (Rozin, 1996), intergroup relations (Plaut & Markus, 2005), education (Fryberg & Markus, 2006; Li, 2003), work ethic (Sanchez-Burks, 2002), honor (D. Cohen, Nisbett, Bowdle, & Schwarz, 1996; Nisbett & Cohen, 1996), hierarchy (A. Y. Tsai & Markus, 2006), relationships (Adams, 2005; Fiske, 1991, 1992), and well-being (Markus, Curhan, & Ryff, 2006; Plaut, Markus, & Lachman, 2002).

For example, people engaging in working-class (WK) contexts are more likely to inhabit social and material worlds that afford fewer resources, less opportunities for control and choice, and more interdependence with family and kin than do people engaging in middle-class (MD) contexts (Markus et al., 2005; Snibbe & Markus, 2005). As a consequence, people in WK contexts are less disturbed than those in MD contexts when others usurp their ability to make a choice, because choice making, and the self-expression and control over environmental contingencies that it affords, does not structure what it means to have a good and normatively appropriate self in WK contexts (Snibbe & Markus, 2005). Moreover, WK ideas about the right way to be in the world are more likely to foster a model of well-being focused on interdependent relations with close others (predominantly family and kin), and adjusting to obligations rather than a model of well-being focused on developing and expressing the self—the model most prevalent in MD contexts (Markus et al., 2005). Most importantly, these differences are reflected not only in the psychological processes of those engaging in MD and WK contexts but also in everyday cultural products—including, for example, popular song lyrics and magazine advertisements—that contribute to the structuring of WK and MD worlds, replete with different meanings, practices, and structures communicating how to be and what kinds of self and life are normal, valued, and good.

Sociocultural models organize the interplay between the more discrete elements of the sociocultural and the psychological systems identified in the mutual constitution model of culture and psyche (see Fiske et al., 1998) and described previously. For this reason, the schematic reflecting this approach contains one large, bidirectional arrow linking *P* and *SC* (Figure 1.1). Through the bidirectionality of

this large arrow, we represent the theoretical and empirical attention paid to the mutual constitution process itself by researchers utilizing this approach. The center of the arrow is composed of several lines, intended to represent the variety of ways in which difference levels of the sociocultural systems (i.e., pervasive cultural ideas and the institutions, products, and everyday practices that reflect and promote these ideas) and the psychological system sustain and foster one another. Since the cultural models approach attempts to delineate the process of mutual constitution by organizing how cultural patterns both exist and necessarily depend upon how they are manifested and made real both “in the head” and “in the world,” this approach focuses on the constitution process itself. Additionally, the relative emphasis placed on *SC* and *P* in this approach is comparable.

Like the tool kit approach we discuss next, the models perspective contests the content-process distinction, in that culture does not enter the psychological by influencing the basic psychological system, but rather is deeply involved in the constitution of the psychological itself. What is universal, from this perspective, is that humans are most fundamentally social beings whose psychological processes are interdependent with and dependent upon the social worlds with which they engage. The models approach, however, does need to specify more clearly the mechanisms by which the mutual constitution of the cultural and the psychological occur, which researchers have largely addressed thus far only at fairly broad levels. It also needs to empirically specify how the cultural and psychological systems exist in dynamic interaction with one another. Though this approach emphasizes this point theoretically, it should further address empirically how people engaging in contexts also shape the cultural, as well as how these constituting systems change over time. Furthermore, the models approach needs to outline more clearly and empirically test the relationship between the material products that structure sociocultural contexts and the minds that engage them.

*The Tool Kit Approach:
A Focus on Culture and Cognition*

Culture can also be thought of as an interpretive tool, or set of interpretive tools, that guide the ways individuals perceive and construct

meaning in the world. The “culture as tools” approach builds on the early work of Sapir (1956) and Whorf (1956). The tool kit of any given culture, explains Bruner (1990), “can be described as a set of prosthetic devices by which human beings can exceed or even redefine the ‘natural limits’ of human functioning” (p. 21). Culture may be best conceptualized as a cognitive tool kit in three primary ways (Nisbett, Peng, Choi, & Norenzayan, 2001). The first is that even if all cultural contexts

possessed essentially the same basic cognitive processes as their tools, the tools of choice for the same problem may be habitually very different. People may differ markedly in their beliefs about whether a problem is one requiring use of a wrench or pliers, in their skill in using the two types of tools, and in the location of particular tools at the top or the bottom of the toolkit. Moreover, members of different cultures may not see the same stimulus situation “in need of repair.” (Nisbett et al., 2001, p. 306)

The second is that “cultures may construct composite cognitive tools out of the basic universal tool kit, thereby performing acts of elaborate cognitive engineering” (p. 306). Nisbett and colleagues (2001) offer Dennett’s (1995) characterization of culture as a “crane-making crane,” citing the transformation of ancient Chinese ideas about yin and yang into more complex dialectical concepts about change, moderation, relativism, and the necessity of multiple viewpoints.

A third perspective that Nisbett and colleagues (2001) promote, is a “situated cognition” view of the cultural tool kit, citing Resnick’s (1994) claim that “tools of thought . . . embody a culture’s intellectual history” and that these tools of thought “have theories built into them, and users accept these theories—albeit unknowingly—when they use these tools” (pp. 476–477, as cited in Nisbett et al., 2001). For example, people who participate in Western contexts, propose Nisbett and colleagues, have chronically been exposed to an intellectual history, beliefs, and theories about how the world is structured that emphasize object discreteness and attributes, the development of rule-based categorization systems, individual agency, personal freedom, control, causality, and abstraction. Alternatively, people who engage in East Asian contexts have been chronically exposed to intellectual history, beliefs, and theories about how the world is struc-

tured that emphasize object continuity and relationships, as well as identify systemic interconnection, collective agency, social obligation, harmony, intuition, and practical empiricism. Thus, one consequence of the continued influence of this contextual variation is that East Asians tend to adopt a more holistic cognitive style, which directs attention toward continuity, context, and a focus on similarities and relationships, whereas Westerners tend to adopt a more analytic cognitive style, which directs attention toward discreteness, focal objects, and a focus on categories and rules.

In a particularly intriguing example of the mutual constitution of cultural patterns and perceptual tendencies, Miyamoto, Nisbett and Masuda (2006) demonstrated that Japanese street scenes are more ambiguous and contain more elements than American street scenes. The implication is that Japanese physical environments may thus encourage a more holistic processing than American scenes. A study exploring this idea found that, when primed with Japanese as opposed to American scenes, both Americans and Japanese attended more to contextual information.

The tool kit approach has also been applied to studies on predictions of change (Ji, Nisbett, & Su, 2001), context sensitivity (Masuda & Nisbett, 2001), reasoning about contradiction (Choi & Nisbett, 2000; Peng & Nisbett, 1999), preferences for formal versus intuitive reasoning (Norenzayan, Smith, Kim, & Nisbett, 2002), and judgments of causal relevance (Choi, Dalal, Kim-Prieto, & Park, 2003). The recent work of Medin, Atran, and colleagues (Atran et al., 2005; Medin & Atran, 2004), with its emphasis on the role of inferential and developmental cognitive processes in preparing people to participate in cultural life, also fits the culture as tool kit approach.

The tool kit approach, which is not entirely separate from the sociocultural models approach, focuses primarily on how culture—broadly construed—shapes the cognitive and perceptual systems. The mechanism of constitution in this approach is how culture functions as an interpretive tool or set of interpretive tools that guide attention and perception (Figure 1.1). This approach challenges the notion that perceptual and other such fundamental cognitive processes are uniformly part of the “basic” human mind by demonstrating that culture can guide such basic processes, rendering the content-process distinction extremely

problematic. Culture, therefore, does not function as an overlay on basic cognitive processes; rather, it is involved from the bottom up and may significantly shape even the most fundamental psychological processes.

Although offering a perspective on the cultural constitution of basic cognitive processes, the tool kit approach does not focus on specifying how the broad sociohistorical patterns that researchers identify to account for observed differences are made current or are continually and dynamically manifested in the institutions, practices, products, and daily experiences of people participating in present contexts. Although researchers utilizing this approach certainly attend to characterizing contexts by identifying prevalent, broad sociohistorical patterns, they frequently move directly to ascertaining very specific psychological effects. Thus this perspective has been criticized for a lack of attention to the constitution process itself, which could lead to an interpretation of this research as essentializing differences even though this is not the intent. It is for these reasons that the schematic representing this approach (see Figure 1.1) does not comprise one large, multilevel arrow encompassing *SC* and *P*. The arrow from *SC* to *P* is bold because this aspect of constitution has been highlighted much more than the ways in which the psychological constitute the cultural (represented by the dashed arrow) though this direction of constitution has been the target of some theorizing.

The tool kit approach primarily focuses on investigating how culture may interact with the cognitive system, rather than also examining the affective, motivational, and behavioral systems, thereby privileging the notion that the sociocultural interacts with the psychological via the cognitive system. In the schematic reflecting this approach, therefore, the *P* representing the psychological is large relative to the *SC*. This indicates that the tool kit approach appears to locate culture as more “inside the head” of the person rather than as engaged in constant and dynamic interaction with present social contexts, material worlds, and the psychological system.

The Ecocultural Approach: A Focus on Adaptations to Ecological and Sociopolitical Contexts

Another approach related to the models perspective, though somewhat different in scope, emphasis, and empirical methods, is the eco-

cultural approach. Proponents of the ecocultural approach, primarily developed by Berry (1976, 1979, 2000), and related ecological perspectives on culture (e.g., Bronfenbrenner, 1979; Whiting & Whiting, 1975), aim to understand how cultural and psychological processes interact by examining how two particular aspects of cultural context—ecological and sociopolitical factors—and a set of variables that connect these factors to psychological processes—cultural and biological adaptation at the population level, as well as several transmission processes at the individual level (e.g., enculturation, socialization, acculturation)—affect psychological functioning and behavioral variation. The ecocultural framework accounts for both cultural and psychological diversity among humans as adaptations—both collective and individual—to particular contexts (Berry, Poortinga, Segall, & Dasen, 2002; Georgas, van de Vijver, & Berry, 2004). Thus, ecological and sociopolitical environments are employed as specific, independent context variables that can be utilized to capture the continuous and interactive process by which sociocultural variables interact with a variety of psychological variables (Berry, 2004). The ecocultural approach is based on both a universalist assumption that basic psychological processes are shared across all humans, and an adaptive assumption that cultural variation arises from adaptations to objective requirements of the physical and social habitat, which allow for effective functioning in particular environments (Berry, 2000). Particular attention is paid to the transmission and developmental processes that link ecological and sociopolitical factors to individual psychological functioning (Berry, 2004; Berry et al., 2002).

The ecocultural approach has been utilized to study topics such as variations in the development of cognitive competence and adaptation (Berry, 1976, 2004; Berry et al., 1986), cultural competence (Lonner & Hayes, 2004), spatial orientation (Dasen & Wassmann, 1998; Mishra, Dasen, & Niraula, 2003), acculturation (Berry, 2003), relationships between ecological indicators and psychological variables (Georgas et al., 2004), and cognitive processes (e.g., Berry, Irvine, & Hunt, 1988). An example of this approach is a study of how ecology and language affect performance on spatial cognitive tasks (Mishra et al., 2003). Variations in spatial orientation systems, and the language that corresponds to such variations, are adap-

tive to the ecological conditions that arise in particular contexts (Mishra et al., 2003). Thus, the predominant spatial orientation style utilized in a flatland village near Varanasi, India, where cardinal directions are employed; in a mountainous village in Nepal, where relative directions are employed; and in the city of Varanasi, India, where a variety of spatial references are employed in response to the more complex environment, differentially affect performance on spatial cognitive tasks. Furthermore, the emergence of these tendencies can be traced developmentally, as children progressively learn the normative adult system.

Several research programs that are best classified as examples of the cultural models approach, because of their attention to meanings as reflected in cultural norms and psychological tendencies, might also be included as examples of the ecocultural approach. These programs include the work of Cohen, Nisbett, and colleagues (D. Cohen & Nisbett, 1994; Nisbett & Cohen, 1996; Vandello & Cohen, 1999) on a culture of honor in the American South and that of Kitayama, Ishii, and Imada (2006) on voluntary settlement patterns in Japan and the United States. A focus on the ways in which behavior patterns emerge as adaptations to both the physical and the social environment is an explicit feature of both research programs.

The ecocultural approach aims to link specific aspects of context (ecological and sociopolitical factors) to psychological processes through particular transmission processes. Though the cultural models approach emphasizes this focus as well, researchers utilizing the ecocultural approach have striven to concentrate on delineating the effects of particular aspects of the context on the psychological system. Furthermore, the attention paid to cultural transmission processes—also emphasized in cultural models theory, but significantly needing more consideration and clarification—is foregrounded. The ecocultural approach, however, assumes that “basic human characteristics are common to all members of the species (i.e., constituting a set of psychological givens), and that culture influences the development and display of them (i.e., culture plays different variations on these underlying themes)” (Berry, 2004, pp. 6–7). Common underlying universal psychological processes are thereby taken as a set of psychological givens, because expressive variation leads to some cultural differences in psycholog-

ical functioning depending on environmental influence (Berry, 2000). Culture is therefore allowed to constitute some of the psychological system, but it does not go “all the way down.”

Although criticized earlier for being environmental determinists who conceive of culture in a largely static fashion, ecocultural perspective theorists now conceptualize people as agents who actively interact with and change their dynamic environments, as ecological adaptation functions as both a continuous and an interactive process (Berry, 2004). Proponents of the ecocultural approach also utilize the notion of context variables (e.g., ecological and sociopolitical factors) as a means to conceptualize culture as an independent variable. Problems with conceptualizing culture as an independent variable have been argued extensively elsewhere (Fiske et al., 1998; Shweder, 1990), and although their goal of specifying how particular aspects of a context may interact with the psychological is important, the idea of culture as a complex, mutually reinforcing, multicomponential system should not be lost. In this approach's schematic (Figure 1.1), *ecology* is highlighted as shaping how *SC* and *P* may constitute one another. The arrow representing how *P* constitutes *SC* is dashed because this aspect of the ecocultural perspective has not yet been underscored in theory and research. *P* is also somewhat larger than *SC* because ecocultural theorizing has placed more relative emphasis on conceptualizing *P*.

*The Dynamic Constructivist Approach:
A Focus on Culture's Situational Influence*

Researchers who adopt a dynamic constructivist approach aim to emphasize that culture resides in the mind in the form of a loose network of knowledge structures, mental constructs, and representations that are widely shared within a given context, and that these internalized constructs do not continuously guide our information processing but rather do so only when activated (Hong, Benet-Martinez, Chiu, & Morris, 2003; Hong & Chiu, 2001; Hong, Morris, Chiu, & Benet-Martinez, 2000). Culture therefore affects cognition when, in particular social situations, the relevant implicit theories or shared assumptions are available, accessible, salient, and applicable in the situation (Hong et al., 2003; Hong & Chiu, 2001; Hong et al., 2000). Hong and Chiu (2001) propose that cultural influences on cognition are “mediated by

the basic principles of social cognition” and activated in specific domains across particular situations; thus, they “seek to identify when well-documented cultural differences in cognitions would surface, disappear, or even reverse” (p. 183). Participants engaging in East Asian contexts, for example, did not differ from participants engaging in American contexts in their propensity to compromise in a decision-making task, unless they were asked to provide reasons for making their decisions (Briley, Morris, & Simonson, 2000). Cultural differences in choice behavior therefore resulted only when participants were required to provide an explanation for their decisions, because “reasons for choices depend on the cultural norms as to what is acceptable and persuasive” (Briley et al., 2000, p. 161).

Expanding on the tool kit idea, described previously, researchers adopting a dynamic constructionist approach emphasize that the applicability of context-based interpretive tools depends upon a specific combination of factors or boundary conditions. Applying a “culturally shared cognitive tool” may be more likely when a person is under high cognitive load or when quick decisions are required, for example, because a spontaneous reaction, rather than deliberative consideration, is more likely to emerge in those types of situations (Hong & Chiu, 2001). When exposed to such conditions, “perceivers are likely to draw on the well learned, widely shared, highly accessible cultural theories to guide their judgments” because perceivers will possess “less cognitive resources and a high need for closure” (Hong & Chiu, 2001, p. 189). Several studies support this idea that cognitive busyness and the need for spontaneous responses augment the potential to observe cultural differences (Chiu, Morris, Hong, & Menon, 2000; Knowles, Morris, Chiu, & Hong, 2001; Zarate, Uleman, & Voils, 2001).

In this approach, the sociocultural interacts with the psychological when a particular knowledge structure, among a loose network of knowledge structures, is activated in accordance with the tenets of basic social cognition principles (see Figure 1.1). The dynamic constructivist approach thereby provides a precise, mechanistic account of cultural influence, with a particular emphasis on variation due to the situational factors and boundary conditions of cultural effects. Thus, *P* in this schematic is quite large relative to *SC* because of the

centrality of basic social cognitive theory in this perspective. *Situation* is also highlighted because the situational must first activate *SC*, as presented by the solid vertical arrow pointing to the solid horizontal arrow linking *SC* and *P*. Situation will influence *P*, then, only when situational conditions are ripe. The other four approaches consider issues of situational dynamism fairly infrequently, and in order to have a more complete understanding of how the cultural and the psychological interact, it is important to understand how such factors play a role in modifying cultural influence on the psychological. The focus of this approach, however, is on cultural *influence* more so than the process of mutual *constitution*, because its aim is to specify the conditions under which the cultural influences the psychological, rather than focusing on the processes by which the cultural and the psychological constitute one another.

Thus, this approach aims to promote the notion that “dramatic effects can involve comparable processes,” in that “while concrete aspects of process differ qualitatively, more abstract aspects of process operate similarly across cultures” (Chiu et al., 2000, p. 257). Chiu and colleagues thereby propose that contrasting cultural variations and universal processes are less productive than modeling the dynamic interplay of culture and mind. Yet with what sort of “mind” is “culture” interacting? Though proponents of the tool kit and models approaches, which focus primarily on constituting processes (though in different fashions), are by no means “merely relativistic,” both do argue for the notion that the psychological system at very basic levels is shaped by the sociocultural. Alternatively, proponents of the dynamic constructivist approach seem to imply that the psychological system is, at core, basic and universal. The dynamic constructivist perspective therefore appears to propose that there is a basic psychological system present with which culture sometimes interacts. This is another reason why the *P* in the dynamic constructivist schematic is relatively large. Moreover, by conceptualizing culture mainly as an interplay between cognitive processes, this approach appears to locate culture primarily “in the head” of the person. The mind is therefore connected to the context only when the social-cognitive conditions are ripe, and that mind seems likely to be a “basic human mind” rather than a “socioculturally contingent mind.”

Comparing Approaches: An Example

The previous section identified and briefly sketched some features of five major approaches to capturing the dynamic interdependence between the psychological and the sociocultural. The approaches have various strengths and weaknesses, and their usefulness is likely to depend on the problem under study. Whether one approach will prove superior to others or whether the approaches will be eventually amalgamated as researchers have a better grasp of both *P* and *SC* is an unanswered empirical question. Analyzing a single problem from the perspective of all five approaches can highlight their differences. A current problem of both theoretical and practical significance is how to understand the differences in academic performance of students with different racial and ethnic associations. In some California schools, but not others, white students and Asian students perform strikingly better in terms of grades and standardized test scores than black and Latino students (Steele et al., 2006). Importantly, in some schools matched for socioeconomic status and curriculum, such disparities are attenuated; thus, differences in performance are primarily or only about differences in relevant skills. Most researchers who are aware of the literature on racial and ethnic gaps in performance would begin with one sociocultural approach or another, assuming that the explanation for these differences is to be found in the interdependence among selves and social systems.

A *dimensional* approach to this problem might be the most straightforward and easiest to assume. It would hypothesize that differences in academic performance result from differences in underlying beliefs, attitudes, and behaviors, and would develop a questionnaire with some well-validated measures to be given to these students. Based on previous research (Katz, 1987), such a study would likely reveal no important differences among these groups of students in how education is valued; almost all students in every context value education and believe in its importance for upward mobility. Questionnaires assessing self-construal, individualism–collectivism, mastery, control, or psychological well-being may reveal differences in how students generally think about themselves. To explain which aspects of culture have produced these differences, investigators might examine the attitudes and values of

teachers or peers toward the students and schooling.

A *sociocultural models* approach would be likely to examine how students are thinking about themselves, their school, their teachers, and the other students. A focus in this analysis would be on the prevalent meanings or implicit norms that are structuring agency and guiding action. Questions might assess what school means to the students and what academic performance means to their views of themselves. Investigators taking this approach might also assess how teachers, parents, or other students are thinking and feeling about the students. A models approach is more likely than other approaches to begin with collecting qualitative data—with not only observations of students in the classroom but also open-ended questions that would allow students to construct their performance in their own terms, using their own words. The assumption of a cultural models approach would be that the school climate does not afford all students a sense of self as normatively good or appropriate; thus, the performance of some students is impaired. A qualitative approach might be combined with the use of vignettes or experimental techniques that would manipulate how students understand themselves or what students believe others understand about them. A models approach might also include an analysis of cultural products such as curricula, school mission statements, assignments, materials on display in the school, teacher practices, and social relations in the classroom. The assumption behind these analyses would be the need to assess the public and private meanings that are prevalent in the school, and to assume that these meanings cannot merely be reduced to or explained in terms of any other factors.

A *tool kit* approach would attend to the attentional and cognitive styles of students, hypothesizing that because of the ideas about learning in their respective contexts, or because of the habitual tasks to which they have been exposed, students from different racial or ethnic groups may have different tools in their tool kit, or may differ in how accessible their tools are. Researchers would be likely to administer a variety of tests to determine how the cognitive processing or attentional skills of the students vary. This approach would work reasonably well for explaining some of these differences. White and Asian students, compared with black and Latino students, are

likely to have relatively higher socioeconomic status, and thus more experience in settings with people who have had more formal schooling, and with tasks and activities that would develop the type of tools required by formal schooling. Investigators might study how various habitual practices in home or previous school environments have given rise to these differences in tools for high grades and test scores.

An *ecocultural* approach would begin with careful attention to the details of the classroom and school situation, perhaps noting classroom size and layout, school size, and ethnic and racial composition of the school and neighborhood. Such an analysis might collect data on the economic level of the school, determining, for example, how many children receive free lunch or other aid. Furthermore, such an approach might also assess the level of teacher preparation in the schools and per-pupil level of school funding, and even the political climate in the neighborhood of the school or the region, including racial and ethnic attitudes. The assumption behind these analyses would be that differential academic performance is a function of how effectively students adapt or are helped to adapt to relevant sets of ecological and sociopolitical factors.

A *dynamic constructivist* approach would not use the wide-angle lens of the ecoculturalist, but would instead zoom in on the immediate situation in the classroom. Such an analysis might begin with the assumption that the differences among students relate to something that happens in the classroom either at the time of the test or at the time of completing or grading the assignment—the situation. Like much research in mainstream social psychology, it is this situation that activates and makes salient different ideas or knowledge, which then produce differences in performance. A dynamic constructivist approach might assume that something is happening in the classroom around academic performance. Perhaps some set of situational factors is producing contingencies between school performance and identity, such that some students feel threatened, devalued, or limited in the classroom and do not perform well. The source of the differences among racial and ethnic groups for the dynamic constructivists would be in some details of the situation and the knowledge structures this situation primes. Proponents of this approach would assume that these group differ-

ences would not be observed at other times in other situations. Dynamic constructivists might experiment with creating different types of situations or with making different ideas, knowledge structures, and self or other conceptions salient, then observing performance.

All five approaches could be useful for the analysis of this problem. None are irrelevant, and the best results are likely to come from using a variety of approaches in combination. All of the approaches could be used to illuminate the full cycle of mutual constitution, but most have yet to attend carefully to how the sociocultural and the psychological interact. Some investigators taking a sociocultural models approach have made some effort to demonstrate how the practices and products generated by people in particular contexts foster particular psychological tendencies, but the other approaches have yet to focus on how culturally shaped people *shape* their contexts. For example, the dimensional approach has not examined how the expression of particular attitudes and values creates and maintains particular contexts. Several other points of tension among the approaches are obvious. An ecocultural approach assumes that the psychological is universal, and that differences among people result from differences in how successfully people have adapted to the various structural characteristics of their situations. A cultural models approach insists that meaning cannot be reduced to the structural, and that it is its own independent level that requires analysis. For example, for students to benefit from a structural variable such as small class size or a factor such as teacher attention, they must attach the relevant meaning to this act; they must construct it as a sign of attention or an indication of high expectations, and they must value such an expression. Such constructions are not automatic; they are contingent on prior constructions. Just as meanings must be expressed in practice or institutionalized in structures before they are powerful, so must structures be animated by particular meanings before they have particular effects.

Among other differences, dynamic constructivists are likely to investigate the details of the classroom. Some students, for example, may perform better when collaborating rather than when working independently, and changing the configuration of the classroom may be one possible route to improved performance. Yet if a relational way of being involves a complex of

attitudes, values, practices, activities, and behavioral orientations, changing behavior may require more than activating an interdependent mind-set or set of knowledge structures relevant to interdependence. At the same time, dimensionalists may fail to see how different situations could in fact prime different norms or values and produce changes in performance. Moreover, the approaches differ somewhat in how likely they are to locate the source of performance in the student. The tool kit approach is probably particularly likely to do so, even though the particulars of the tools depend on the context. The ecocultural and sociocultural models approaches are less likely to do so. All of these approaches could directly assess the views that others have about the students and locate at least some of the performance differences in the eyes of others or in what students perceive as the expectations that others hold for them. Such measures may be more powerful predictors of performance than measures taken of the students' views of themselves.

A key aspiration of a sociocultural perspective, regardless of the particular approach to mutual constitution, is to go beyond the person in explaining the person. Many important effects are likely to be located in intersubjective space and are the result of what the target person is thinking that another person(s) is thinking about her or him. Finally, although these approaches have so far been identified by different methods, all of the approaches to mutual constitution could profitably use all methods.

A Note on Mechanism and Mediation: Toward Specifying How It Works

Mutual Constitution Mechanisms

What are the mechanisms that fashion the interplay between the sociocultural and the psychological? In a broad sense, repeated mere exposure (Zajonc, 1968) certainly applies, in that particular contexts afford exposure to certain meanings, practices, and institutions that constitute the fabric of our social worlds, and in that exposure leads us to construct these certain meanings, practices, and institutions as familiar, normal, and good. Sperber (1996) further contends that representations that are "repeatedly communicated," while being "minimally transformed" in a given context, end up "belonging" to a culture. Thus, exposure to meanings and practices prevalent in a

given context can provide a network of implicit and explicit associations to guide what it means to be a good person and competent social actor in that context, such as models of agency (Markus & Kitayama, 2003) or models of self (Markus et al., 1997). Kitayama and colleagues (Chapter 6, this volume) suggest that, in particular, the patterning of social relations prevalent in a context affords a particular principle of action regulation, such as goal directedness versus responsiveness to social contingencies, which then guides an array of related psychological tendencies and behaviors. Thus, social relations in East Asian contexts, oriented toward interdependence and collectivism, direct people participating in such contexts to attend to the external contingencies of relating with others, such as others' expectations, desires, and needs, as well as particular features of the social situation, such as whether one is situated in a work or home context. Therefore, to behave as a competent social actor, individuals are motivated to respond to such social contingencies, adjusting their behaviors accordingly.

Cultural models, therefore, seek to organize how certain meanings and practices that are pervasive in a context structure the individual's psychological world. Individuals engaging in particular contexts in turn embody, reproduce, contest, and transform these prevalent contextual patterns. Thus, both the psychological and the contextual are conceptualized as interacting systems: The context is a system that comprises meanings, practices, institutions, and daily experiences, whereas the psychological is a system of behavioral, cognitive, affective, and motivational processes, often organized as a self-system. Even the act of contesting or rebelling against a prevalent cultural pattern, such as choosing to devote one's self to the hyperindividualistic teachings of Ayn Rand despite growing up and currently living in a relatively collectivistic Japanese context, nevertheless involves a deep level of engagement with that particular cultural pattern. Though much cultural patterning of the person does take place at the implicit level, to engage with and be shaped by a cultural model does not imply that an individual does so as a mindless automaton.

Acquired attentional strategies are another broad-level mechanism by which the cultural and the psychological interact (Nisbett et al., 2001). Such strategies, which derive from the

interplay between context-specific, naive meta-physical and epistemological systems and cognitive processes, can serve to direct individuals' perceptual processes, thereby shaping (at least in part) the cognitive tool kit available to people participating in given contexts. These acquired strategies guide the information about the world on which the perceptual system focuses, and thereby the information available for cognitive processing (e.g., Hong & Chiu, 2001; Hong et al., 2000; Ji et al., 2001; Kitayama, Duffy, Kawamura, & Larsen, 2003; Masuda & Nisbett, 2001; Nisbett et al., 2001). Nisbett and colleagues, for example, propose that enduring differences in the cognitive styles of people participating in Western versus East Asian contexts support the interplay between cognitive processes and historically derived beliefs and theories about how the world is structured. These differences both render and reinforce distinct systems of thought.

These attempts at delineating the mutual constitutional mechanisms that guide how the dynamic interdependence between the socio-cultural and psychological functions have in common an attempt to capture how the cultural and the psychological exist in constant, dynamic interaction with one another. They attempt to organize how the sociocultural and the psychological shape and require one another. The cultural models approach and the tool kit approach tend to focus on broad constitutional mechanisms of exposure and attentional orientation, with the intent of identifying how mutual constitution takes place. The cultural models approach tries to organize how different levels of the cultural system (core cultural ideas and representations, institutions, practices, products, and daily experiences) interact with different levels of the self-system (affect, cognition, motivation, and behavior). Researchers employing the tool kit approach predominantly do not focus on how the cultural and the psychological are mutually constituted through the different levels of the cultural system; rather, they focus on how sociohistorical differences in context may be reflected in the most basic levels of the cognitive system.

Mechanisms That May Mediate the Relationship between the Cultural and the Psychological

In further attempts to clarify how the cultural and the psychological work together, research-

ers have also aimed to specify some of the mediating mechanisms by which the cultural and the psychological interact. Hong and colleagues (Hong et al., 2000, 2003; Hong & Chiu, 2001) suggest that culture interacts with the psychological in a situational manner, according to the basic social-cognitive principles of availability, accessibility, saliency, and applicability. According to the dynamic constructivist approach, culture, at the psychological level, resides in the mind in the form of domain-specific knowledge structures or implicit theories; thus, “cultural differences are mediated by the activation of cultural theories” and cultural differences in self-cognitions and social behaviors “emerge only when relevant cultural theories are activated” (Hong, Ip, Chiu, Morris, & Menon, 2001, p. 260). In a formal mediation analysis framework, for example, Briley and colleagues (2000) found that the content of participants’ reasons for a decision—whether the reason was compromise-oriented or not—mediated the relationship between consumer cultural background and their preference for compromise alternatives. Furthermore, individualism–collectivism and conflict resolution style, both individual difference or dispositional measures, were not found to mediate the cultural effect (Briley et al., 2000).

Moreover, the effects of culture on the psychological may be attenuated or enhanced due to particular boundary conditions on cultural influence (Hong & Chiu, 2001), such as need for closure (NFC; Chiu et al., 2000). Whether existing chronically (Chiu et al., 2000), or induced via time pressure (Chiu et al., 2000) or cognitive load (Knowles et al., 2001), people high in NFC demonstrate magnified cultural differences. Thus, “another kind of evidence for cultural differences in chronic accessibility hinges on the interaction of accessible constructs with epistemic motives” (Hong et al., 2003, p. 454), in that the desire or need for a clear answer to a question and a dislike for ambiguity lead the individual to rely on well-learned, repeatedly rehearsed, highly accessible—and thereby potentially cultural—constructs (Chiu et al., 2000). Thus timing, when culture influences the psychological, is a central theme characterizing this stream of research.

The moderating effects of NFC, suggest Chiu and colleagues (2000), may be mediated by the immediacy principle, or the epistemic

need to reach any decision quickly regarding an ambiguous issue. Because cultural theories are not the only way an individual understands the social world, and “do not emerge out of a motivational vacuum,” people engaging in various contexts can “develop and apply a cultural theory to meet their epistemic needs” when necessary (Chiu et al., 2000, p. 10). Epistemic needs may generally derive from the individual’s attempt to make sense of the reality of daily life, which is often ambiguous (Adams & Markus, 2004; Richter & Kruglanski, 2004). Another articulation of how cultural influence may be the result of motivated cognition comes from terror management theory, in that cultural theories help people make sense out of the “big questions,” such as the meaning of life (Pyszczynski, Greenberg, Solomon, Arndt, & Schimel, 2004). Religion, for example, is a cultural institution that offers solutions for the potentially paralyzing, existential terror induced by the awareness of one’s mortality. People are thus motivated both to construct and to engage in such institutions that embody particular cultural patterns (Solomon, 2004).

Self-construal, another significant mechanism proposed to mediate and cause cultural effects, was originally proposed as an organizing device, able to capture the interplay among cognitive, affective, and motivational systems that may comprise how a person in a given context construes the self, and how the self relates to others in similar or differing modes across cultural contexts (Markus & Kitayama, 1991). Although some researchers have maintained studying the self in a systems framework (Cross & Madson, 1997; Heine et al., 1999; Kitayama et al., 1997; Markus & Kitayama, 2003; Markus et al., 1997), and have directed their research at understanding the mutual constitution of context and self, others have adopted more social-cognitive approaches geared toward delineating the causal role of self-construal as a cognitive mechanism in producing and/or mediating particular psychological effects. Shifts in self-construal (either priming aspects of independence–individualism or interdependence–collectivism) have been found, for example, to mediate shifts in values and judgments of obligation (Gardner, Gabriel, & Lee, 1999), increase the retrieval of self-cognitions relating to the aspect of the self primed (Trafimow, Triandis, & Goto, 1991), guide whether a context-dependent versus context-independent mode guides cognition

(Kühnen, Hannover, & Schubert, 2001; Kühnen & Oyserman, 2002), determine whether attentiveness to others is a self-defining goal and thereby an enhanced tendency (Haberstroh, Oyserman, Schwartz, Kühnen, & Ji, 2002), determine the consequences of social comparison (Stapel & Koomen, 2001), elicit modes of regulatory focus (Lee, Aaker, & Gardner, 2000), and influence mimicry behavior (van Baaren, Maddux, Chartrand, de Bouter, & van Knippenberg, 2003). These findings often appear to mirror analogous effects observed between unprimed people engaging in different contexts (e.g., North American and East Asian, suggesting that the proposed cultural effects are actually due to some aspect of self-construal; see Cohen, Chapter 8, this volume).

Although the manipulation of self-construal helps researchers strengthen the causal argument in support of interdependent constitution between mind and context, it is unclear whether such cognitive priming effects are truly comparable to chronic contextual effects (see Cohen, Chapter 8, this volume, for an extended discussion). Moreover, in citing previous work, those who have interpreted “selves” to mean explicit concepts that can be assessed directly through attitude or value scales appear to miss the significant point that the self is not a particular set of attitudes, or conscious verbal propositions about the self, that are accessible or even activated reliably on a conscious level; instead, the self is a set of implicit and explicit modes of operating in the world. For example, in an independent mode of operating in the world, behavior is organized and made meaningful primarily by reference to one’s own internal repertoire of one’s own thoughts, feelings, and actions. In contrast, in an interdependent mode, behavior is organized and made meaningful to a large extent by reference to the thoughts and feelings of others in their encompassing social networks. These orienting patterns that guide thought, feeling, and action do not necessarily translate into explicit concepts that can be assessed directly through attitude or value scales (Markus & Kitayama, 2003; Heine & Norenzayan, 2006), though this work is attractive because it “uncomplicates” the complexities of thinking of self and culture as multifaceted interacting systems, and is therefore relatively easy to use (Kitayama, 2002).

Responses to self-report attitudinal scales are not necessarily valid or accurate indices of

cultural constitution, often demonstrating a host of measurement biases and inconsistencies with cultural effects demonstrated on other types of measures (Chen, Lee, & Stevenson, 1995; Heine, Lehman, Peng, & Greenholtz, 2002; Peng, Nisbett, & Wong, 1997), and the primes utilized to induce self-construal effects may not serve as very meaningful proxies for cultural constitution or influence (for recent discussions, see Kitayama, 2002; Heine & Norenzayan, 2006). Furthermore, relatively few precise mediating mechanisms have been identified besides cognitive self-construal (Heine & Norenzayan, 2006), so researchers in the field should be careful not to overprivilege this one potential mechanism.

Also, it remains unclear whether or not self-construal priming in and of itself has the same effects on people engaging in different contexts. Although the researchers cited earlier appear to demonstrate that this may be the case to a certain degree (e.g., Gardner et al., 1999; Trafimow et al., 1991), others have suggested that it may not (Oyserman, Coon, & Kimmelmeier, 2002). Hong et al., (2001), however, found that although priming the individual self (“I”) versus the collective self (“we”) among Chinese and American participants affected spontaneous self-concept, the effect was manifested differently between the two groups. When the collective self was activated for Chinese participants, their awareness of duties was also increased, though this was not the case for American participants. On the other hand, when the individual self was activated for American participants, their awareness of individual rights was also increased, though this was not the case for Chinese participants. The authors propose that because duties are emphasized in Chinese contexts, they are central to the notion of the collective self, but because rights are not emphasized, they are not salient in the individual self-concept. Alternatively, because rights are emphasized in American contexts, they are central to the individual self, but because duties are not emphasized, they are not associated with the collective self-concept. Hong et al. conclude that “although the ‘I’ or ‘we’ manipulation can enhance individualistic or collectivistic orientations regardless of participants’ cultural background, how such manipulation affects spontaneous self-cognitions may depend to a large extent on what constitutes the individual and collective selves in the culture” (p. 260). It

is important to disentangle how situational priming interacts with chronic contextual influence.

Whereas other researchers are beginning to offer accounts that specify the mediating mechanisms that structure the relationship between the cultural and the psychological, such as choice-making perceptions and goals (Iyengar & DeVoe, 2003) and social beliefs (Bond, 2005), the question of how the cultural and the psychological interact is still very open in the field, leaving much room for further exploration. Cohen (Chapter 8, this volume) offers an account of both the advantages and disadvantages of applying formal mediation analysis to cultural-psychological research, which should be considered carefully due to the current emphasis on performing mediation analyses in social and personality psychology. A consideration Cohen (Chapter 8, this volume) highlights that deserves particular attention, is that typical conceptions of the mediation method locate culture within the individual, particularly “inside the head” of the individual. This approach thereby underemphasizes how culture also exists “outside of the person,” built into the sociocultural environments that we inhabit. Cultural researchers also need to consider the possibility of external factors that may mediate the relationship between the sociocultural and the psychological. The worlds that people inhabit are *themselves* cultural products; they are meaning-saturated repositories of the psychological activity of those who preceded us (Adams & Markus, 2004; Bourdieu, 1990; Cole, 1996; Shore, 1996). We need to delineate how meaning-saturated everyday worlds that comprise institutions, practices, experiences, products, and representations mediate how the cultural works on the psychological.

Moreover, it is important to point out that failing to *directly* measure hypothesized causal mechanisms is not unique to the study of sociocultural psychology; in fact this is true in many of the phenomena studied in social psychology (Heine & Norenzayan, 2006). For example, the “dissonance” in cognitive dissonance theory (Festinger, 1957), the “terror” in terror management theory (Pyszczynski et al., 2004), the “threat” in stereotype threat theory (Steele & Aronson, 1995), and the particular computational mechanisms underlying the biases and heuristics that lead people to commit the conjunction fallacy and base-rate neglect

(Kahneman & Tversky, 1973) all deal with hypothesized constructs that have as yet been directly assessed or captured either rarely or not at all through measurement techniques (Heine & Norenzayan, 2006). Thus, sociocultural psychology does not uniquely confront challenges associated with measurement precision, and should not incur special criticism for this issue (Matsumoto & Yoo, 2006).

Culture as “Process” versus Culture as “Social Influence”

Reflecting on the field as a whole, one important distinction that can be drawn regarding the current empirical approaches to studying the relationship between the cultural and the psychological is whether researchers seem to conceptualize culture as *process* or as *social influence*. Conceptualizing culture as process entails emphasizing that it functions as a “constituent process that is implicated in explaining what are considered basic psychological phenomena,” a “source of patterning” for psychological processes themselves (J. G. Miller, 1999, p. 85; 2002). Researchers who view culture as process tend to focus on how one becomes and exists as a cultural being, emphasizing that the cultural and the psychological, the environmental and the individual, cannot be separated. Culture is a symbolically structured environment (Greenfield, 1997), wherein the sociocultural and the psychological exist in mutual interdependence with one another. Thus, neither the sociocultural nor the psychological can be reduced to or extracted from the other (J. G. Miller, 1999).

J. G. Miller (1999) points out that manipulating individualism–collectivism in the lab, for example, does not replicate the nature of cultural constitution that arises from engaging in collectivist contexts, because “cultural variation in psychological functioning arises not merely from individuals maintaining contrasting schematic understandings but also from their involvement in contrasting cultural activities and practices” (p. 89). Researchers who conceptualize culture as a means of social influence, alternatively, may assume that the psychological system is at core basic, universal, and unstructured by the sociocultural; thus, the psychological is influenced by culture only when the appropriate situational conditions arise. This way of conceptualizing culture relies

on more typically social-psychological understandings of social influence (discussed previously) that do not recognize the full extent of the sociocultural constitution of the psychological. The field will need to address the implications of conceptualizing culture as influence or as process, and delineate what can be learned from each perspective to elucidate the dynamic interdependence between the sociocultural and the psychological.

THE SOCIOCULTURAL APPROACH—WHAT NEXT?

Together the studies reviewed here are successful in illuminating some of the ways in which people and their social world make each other up. These studies are a significant start in establishing an empirical foundation for the theoretical vision of some of psychology's earliest theorists. As the sociocultural approach is elaborated, two ideas emerge clearly: (1) Many theoretical and methodological challenges still have to be met, and (2) the sociocultural approach can be extended productively to other areas within psychology.

Conceptual Challenges

The application of a sociocultural approach to psychology makes clear that the dualistic notions of "inside and outside the head" and of "the person and the situation" are frameworks that, though useful in the past, may now impede theorizing. Behavior is not the function of "the person" and "the situation" as separate entities, but is rather the consequence of the dynamic relationship and basic constitutive interdependence between the two.

Persistent Dualisms

The ideology of individualism has been the powerful perspective that has dominated psychology, forcing a divide between "person" and "context," "inside" and "outside." Typically, the actor in a psychological interaction is cast as an entity separate from the external contextual stage, and that actor's internal psychological system is then moved or influenced by the external immediate situation "performed" on that stage. Many theories in psychology conceptualize the person as a bounded, autonomous, independent being who aims to move through the world unfettered by

group ties or situational pressures (for a discussion of these ideas, see Baumeister, 1987; Bellah, Madsen, Sullivan, Swidler, & Tipton, 1985; Farr, 1991; Guisinger & Blatt, 1994; Markus & Kitayama, 1994; Sampson, 1985, 1988; Shweder & Bourne, 1984).

Psychology has thereby taken as normal and natural a fundamentally *asocial* model of the person. The implicit notion that the individual is an a priori separate and self-contained (as well as rational and self-interested) social actor, who must resist or be on guard with respect to control or influence by others, is a key idea in all areas of psychology. A sociocultural approach challenges psychology to consider a more social model of the person, in which the person exists in a dynamic and inextricable bond with her or his context. There is no "neutral" or "natural" person that exists apart from her or his context, or apart from the social construction of her or his existence as a fully functioning self. Similarly, as noted earlier, the situations that are often cast as separate from people cannot be understood as separate from their affording cultural contexts.

These context-contingent patterns of meanings, practices, and products *cannot be isolated from* basic psychological processes and behavior. Despite the clear understanding of the constructed nature of social reality evinced by most early theorists, over subsequent decades psychologists have often described the social world as if it existed independently of the perceiver's standpoint, and was there for perceivers to apprehend either adeptly or speciously. Sapir (1924), arguing against the notion of an external reality existing outside the person, claimed that "the worlds in which different societies live are distinct worlds, not merely the same world with different labels attached" (p. 409). Likewise, Goodman (1984) asserted, "One might say there is only one world but this holds for each of the many worlds" (p. 278).

More recently, some programs of research have begun to move closer to empirically illustrating the many worlds that exist within the one world and to carefully track the ways the idea that the individual and the social world exist in a fundamentally contingent relationship. Nisbett (2003) and colleagues, in the studies we reviewed earlier, have shown that those engaging in European American contexts and those engaging in East Asian cultural contexts *see* the same stimulus in

very different ways, and that the products they produce reflect these differences. Markus et al. (2005) have shown that perceivers in Japanese and American contexts are likely to understand agency in different ways, and their social worlds are constructed accordingly. Thus, perceivers in American contexts saw the performance of Olympic athletes as a function of various athletic strengths and skills, whereas perceivers in Japanese contexts saw the performance of Olympic athletes as equally reflective of athletic strengths, past training, and experience. These differences were not just a matter of different construals of the same athletic performance. The constructed social world also reflected these differences. The respective television coverage of the Olympics (one type of cultural product) incorporated these different understandings of behavior. American coverage contained many more observations of athletic strength by commentators, reporters, and athletes themselves than did the Japanese coverage. Additionally, the Japanese coverage contained more observations about the critical role of training and past experience than did the American coverage.

Universals, Yes; Universalistic Fallacies, No!

One aim of a sociocultural approach is to contest universalistic fallacies and the empirically false assertion that people are more or less the same psychologically, regardless of their historical and sociocultural circumstances. Multiple worlds and multiple psychologies are attuned to reproduce and foster these worlds. Yet all is not relative: A world exists. The distinct worlds that lend structure and meaning to experience in particular and specifiable ways are indeed part of one world, and these distinct ways make contact and have consequences for each other. Thus, identifying some ideas and practices that cross-cut contexts and specify some human universals is also a goal: Similarities and differences have meaning only in the context of each other. For example, with respect to agency, people everywhere experience agency and behave agentially; they act in the world or regulate their own behavior. The psychological system of agency is universal, but the form it takes is culture-specific, because the actual workings of the system are contingent on and afforded by particular symbolic resources and social systems. Agency, then, in its phenomemo-

logical form, is very much socioculturally tailored and sanctioned.

Whereas people engaging in North American contexts experience agency as an autonomous self, intrinsically motivated and engaged in control, influence, and self-expression, people in East Asian cultural contexts are likely to experience agency as an interdependent self, actively adjusting to others' expectations to realize various relational goals and to maintain interpersonal harmony. Whereas the word *doing* seems the best and obvious gloss for agency in North American contexts, the word may carry with it a sense of direct action or of work in the world that may not be equally appropriate in Asian contexts. In these latter contexts, the word *be-ing* may be a better gloss that more accurately reflects the psychological state that accompanies agency. Both modes of doing and being in the world are agentic; however, each context affords a divergent structure for agency—thus, what “counts” as agentic differs.

Much of psychology has been very quick to universalize findings in many domains, doing so before any data that would allow such generalizations exist. Even the division among cognition, emotion, and motivation that comprise the deep structure of the field may in the fullness of time and careful empirical research emerge as a culture-specific commitment that derives from the particular Western philosophical assumptions built into American psychology. Psychology will improve as a science as it assumes a sociocultural approach across the field. Thus, for example, before looking for the evolutionary or the genetic underpinnings of a given behavior, it would seem wise, and also scientifically sound, to determine whether a given observed behavior can still be observed once the context shifts. For the most part, there is no allergy to universals among sociocultural psychologists. Regardless of their particular approach, they are alike in hoping to avoid the premature generalizations and universalistic fallacies that still pervade much of psychology.

Extending a Sociocultural Approach

The Example of Social Identity Research

Many areas within psychology might be more fully theorized and well understood with an approach that explores the interdependencies among self systems and social systems. A good

example of a body of research that addresses many of the same content areas that we have been considering with a sociocultural approach, and could benefit from study under this approach, is the literature on social identity, stereotyping and prejudice. Social identity theories, for example, focus on how selfhood and identity are affected by the groups to which people belong. These studies reveal the ways in which the sociocultural is crucial to identity. In a dynamic process, people categorize and identify with some groups and contrast themselves against other groups. By creating groups (e.g., dot overestimators and dot underestimators) in the laboratory, thus producing a microcosm of the world, social identity researchers have been able to illuminate some of the ways in which social identity is powerfully contingent on the sociocultural context (e.g., Ellemers, Spears, & Doosje, 2002; Tajfel & Turner, 1979).

Being classified as a dot overestimator, for example, creates for the participant some important aspects of the group experience. Yet the laboratory microcosm is better at modeling some aspects of social identity negotiation than others. The fact that the social categorization can be produced easily in the laboratory is theoretically important, but it means that the category being examined is not a category saturated with social meaning and manifest in multiple social practices. Once branded an “overestimator” by the experimenter, the participant will experience an affinity with others so branded, and indeed reveal ingroup bias. This process is critically important for understanding some of the sources of social identity. Yet a given individual will not “be” a dot overestimator in the sense that he or she is recognized, treated, and judged as such by others in a way that has important life consequences. Nor will this categorization carry with it many ideas about what is right, good, true, and normatively appropriate for overestimators across many domains of behavior and social interaction.

The sources of social identity, its societal affordances, and its role in regulating behavior are also critical in research on stereotype threat. In these studies of social identity the psychological is indeed linked to the context; however, it is primarily linked to immediate variations in the configuration of the sociocultural context (i.e., whether one is solo or not, whether one feels safe in the context or instead feels implicitly or explicitly threatened

e.g., see Steele, Spencer, & Aronson, 2002; Taylor et al., 2004). These studies reveal, for example, that being exposed to a commercial with a stereotypical image of a woman—as flighty, emotional, and concerned about the home—is related to reduced performance and aspirations in women (Davies, Spencer, & Steele, 2005). The focus of such research is on specifying the process, in particular, the cognitive process by which threats to social identity alter performance and group identification. Indeed, many features of this process are similar whether the threat is initiated because of gender, ethnicity, age, or weight.

What could be usefully added to such analyses of the social context’s influence are (1) the source and meaning of the threat, and (2) how pervasive, chronic, and well-instituted the threat is in the practices, policies, and products of the larger sociocultural context. The stereotype threat studies persuasively demonstrate that singling out or devaluing some aspect of one’s identity matters for psychological functioning. They clearly link the social with the psychological. Being branded as an intense New Yorker by one’s laid-back Silicon Valley coworkers is a threat to group belongingness to be sure, but is likely to have powerfully different consequences than trying to live a normal life as a gay individual in the U.S. military, where the threat is instituted as official policy. A combination of research on social identity, stereotyping, and prejudice with a sociocultural approach would not only facilitate a more specific and comprehensive understanding of these processes but also extend their applicability and utility.

Links to Stereotyping and Implicit Associations Research

Similarly, the recent surge of interest in implicit attitudes and biases could also be productively harnessed to sociocultural theorizing. Powerful implicit associations, such as those between white and American (Devos & Banaji, 2005) and those between black and criminal (Eberhardt, Goff, Purdie, & Davies, 2004), are extremely common, because they are built into our everyday worlds in multiple incarnations. Such findings locate some of the sources of discrimination and prejudice in the content of the worlds that people inhabit. They offer the optimistic view that important changes in behavior can be produced by changing the meanings,

practices, and products prevalent in the various contexts that originally prompted the behavior. For example, some implicit association test (IAT) findings suggest that the associational space can be rearranged and other associations (black and good) and can be made more available (Richeson & Trawler, 2005). A sociocultural approach would caution, however, that although possible, successful interventions would require considerable sustained effort and resources, because these associations need to be embedded in meanings, practices, and products that are pervasively and chronically distributed throughout everyday worlds to truly change the associational structure of the people who inhabit them.

Links to Racial Formation Theory

Whereas prejudice, stereotyping, racial attitudes, and the effects of categorization by race are among the most important and well-developed areas of research in social psychology, seldom is the phenomenon of race itself directly approached. Most research is silent on what race is or how it has come to be. Nor is there typically discussion about the content of racial categories and ethnic identities. Saying “Race is real,” in the sense of mutually constituted as “real in the world,” invokes a long and pernicious history of essentialism and biological racism. As a result the ways in which race has been constituted and instituted have been largely ignored in social psychology, a field identified from its inception with overcoming stereotyping, and with distancing itself from describing and discussing group differences; it is not surprising that scholars would focus on the consequences of racial ascription rather than confront ideas of how race is constructed and made real in everyday social worlds. Instead, the focus has been on stereotypes, with the implicit assumption that if people could be purged of their negative racial attitudes and implicit biases, all would be well, because racism “is in the head.”

Yet a sociocultural approach to race reveals that even if people’s heads were free of racial prejudice, what would be left is the material world—a world replete with prejudicial representations, practices, policies and products, such as popular movies and television, saturated with stereotypical images, racial profiling, segregated housing, biased hiring practices, and unequal credit policies and

opportunities to secure loans. These stubborn social facts would continue to exert their effects on the psychological and would soon reconstitute the familiar implicit and explicit prejudicial processes.

Race, then, can be understood as a sociocultural context itself—a matter of social structure and cultural representation that can be productively analyzed using a sociocultural approach. Sociologists (Omi & Winant, 1994) who began such an analysis of race have analyzed race as a “sociohistorical process by which racial categories are created, inhabited, transformed, and destroyed” (p. 55). Racial formation, they argue, “is a process of historically situated *projects* in which human bodies and social structures are represented and organized” (p. 56; emphasis in original). In their theorizing they connect meanings (i.e., what race means) with status and power, and the ways in which social structures and everyday experiences are organized based upon such meanings. In short, extending the sociocultural approach to race is useful because it highlights the central idea of this chapter. Phenomena such as stereotyping, discrimination, and racism cannot be located either solely in stereotypes inside individual heads or solely in inert social structures.

CONCLUDING COMMENTS

We have explained in this chapter that a sociocultural approach is signaled by the view that people and their social worlds require each other and should be analyzed together. The signature of this approach is not a particular method, set of methods, but rather an emphasis on interdependences among the person and the sociocultural system. Defining features of this approach include a concern with thinking beyond the person and attending to meaning-making processes and how meanings are manifested and maintained in the worlds people inhabit. Notably, a sociocultural approach does not require an explicit comparison between two or more contexts. Such a comparison affords an appreciation of the role of the symbolic resources and social systems in constituting selves and action, but it is not essential to all sociocultural questions. Once an understanding of the ways in which psychological systems are grounded in, and afforded by, meanings, practices, and products is achieved,

this approach can be applied to the analysis of any problem (e.g., aggression, violence, obesity, depression).

Psychological functioning, being a self or an actor in the world, is contingent on the symbolic resources and the patterns of social life distributed among the various sociocultural contexts in which a person engages. The precise nature of this contingency remains to be empirically determined, but a sociocultural approach highlights that this contingency is the nature of human beings. Very important insights into human functioning are being produced rapidly, for example, by current neuroscience methods, but no matter how precise and well-specified, a focus on the person will tell only half the story. In closing, this review of the principal sociocultural approaches, and the promising research generated by these approaches, convincingly supports Bruner's (1990) assertion that it will be impossible to construct a comprehensive psychology on the basis of the human alone. The radical vision of some of psychology's original thinkers—specifying how biological beings become *human* beings through their engagement with the meanings and practices of their social world—is becoming a well-grounded empirical reality.

CHAPTER 2

Anthropological Foundations of Cultural Psychology

ROBERT A. LEVINE

This chapter examines the roots of cultural psychology in the anthropology of the 20th century and explores the varied ways in which contemporary social anthropologists approach problems relating culture and psychology. Contemporary cultural psychology is partly an outgrowth of the American anthropology of the mid-20th century (1925–1975), which formulated, explored, and investigated the concept of culture, relationships between psychological and cultural characteristics, and culture-specific conceptions of person, self, mental processes and psychopathology, using ethnographic, linguistic and clinical methods. In this chapter I review some of this history, particularly to call attention to a little-known, earlier literature that dealt with conceptual and methodological issues that remain problematic in current research.

My focus is on the emergence of fundamental concepts, the controversy over the individual or collective locus of culture, and the methodological division between “objective” and “subjective”—or statistical versus clinical—approaches to psychocultural phenomena. I argue that the intellectual fault lines that developed in anthropology during the 1930s grew wider in successive decades and challenged

psychological anthropologists to build the bridges represented by recent interdisciplinary work.

Although my historical narrative gives primary attention to the intellectual legacy of Franz Boas and Edward Sapir, as it affected later generations of American anthropologists, this limitation does not represent a judgment that the British influences of W. H. R. Rivers, C. G. Seligman, and Bronislaw Malinowski (Stocking, 1995) or the development of cognitive anthropology documented and interpreted by Roy D’Andrade (1995) are unimportant. My primary concern is to present the Boas–Sapir legacy in the terms made possible by the historical research of George Stocking (e.g., 1968, 1992), Regna Darnell (1990, 2001), and Judith Irvine (Sapir, 1993), who have retrieved and illuminated this line of thought from documents and oral history. My account is also affected by my personal communications in the generations following Sapir with anthropologists who attempted to translate his approach into empirical research (John and Beatrice Whiting, Clyde Kluckhohn, A. Irving Hallowell, Melford E. Spiro, George DeVos, William Caudill, Anthony F. C. Wallace, George and Louise Spindler, Gananath Obeyesekere). The

aim is to give cultural psychologists a historical perspective on their own work through an intellectual genealogy in which they can locate themselves as the heirs to problems and methods framed by pioneers of 20th-century anthropology.

BOAS AND SAPIR: THE PSYCHOLOGY OF CULTURE

Franz Boas (1859–1942) and Edward Sapir (1884–1939) laid the most important anthropological foundations for cultural psychology, even though they published little on the subject. In Boas's writings, the theory of culture and psychology is largely implicit. Sapir wrote explicitly but at his death had published only a few papers in this area. Their influence, however, was enormous, and it is mainly through the work of historians and biographers that we have come to understand their thought and how it affected research in psychological anthropology.

Boas is known largely as the leader of American anthropology early in the 20th century and the teacher of those who founded “culture and personality studies” (as psychological anthropology was called up to 1960), namely, Edward Sapir, Ruth Benedict, Margaret Mead, Abram Kardiner, and A. Irving Hallowell. Boas's own writings, however, were mainly on specialized topics in physical anthropology, linguistics, material culture, and folklore, and within those areas, on problems that were at issue before 1914, mostly in Native American studies. Furthermore, most of the many published pages of “ethnography” Boas left behind at his death were unannotated Native American texts recorded for the study of language and folklore (Berman, 1996). Where is the psychology in his publications, apart from the titles of some of his works, such as his famous book *The Mind of Primitive Man* (1911)? George Stocking (1992), the preeminent Boas scholar, has attempted to answer this question.

Boas, as Stocking tells us, was well versed in German psychology before his immigration to the United States in 1887 (when he was 28 years old), and he had published pieces on Fechnerian psychophysics in 1882 (Stocking, 1968). From early in his career, Boas was a radical empiricist who avoided what he regarded as speculative generalization in his writing, so that his publications focused on specific empirical problems, without spelling out his basic

premises concerning culture and its relationship to human psychology. Underlying these particularistic concerns, however, was a grand plan: to replace the speculative theories that abounded in the human sciences during the late 19th century with empirical data drawn from the diversity of conditions—cultural, linguistic, ecological, and historical—in which humans lived.

Boas had a special interest in methods and measurement, and was drawn to research fields in which a corpus of reliable data could be collected, both to falsify a priori speculations and to indicate how diverse environments produced diverse outcomes. Trained in anthropometric methods by Rudolf Virchow, the Berlin biomedical pioneer, in 1883, Boas adopted both Virchow's concept of plasticity as a basic biological principle and his skepticism about theories ungrounded in empirical fact. In Virchow's obituary in *Science* in 1902, Boas denied the charge that Virchow did not accept Darwinian evolution through natural selection. It is undeniable, however, that the skeptical attitude Boas admired in Virchow led the younger man not only to oppose evolutionary proposals in the social sciences but also to rule out the cross-cultural comparisons that he believed led to false generalizations.

Boas saw himself as a biological scientist initiating studies of human variation. At Clark University (1889–1892), where he was hired by G. Stanley Hall, Boas taught a course on statistical methods in anthropology in the anthropology division of Hall's psychology department. Later, when analyzing physical growth data on immigrants to the United States, Boas—who had met Francis Galton, the inventor of correlational analysis—improvised his own forms of correlation, analysis of variance and factor analysis, and corresponded with the statistician Karl Pearson (Howells, 1959; Tanner, 1959). Boas also learned and accepted Mendelian genetics and viewed the physical growth of children as a joint outcome of genetic and (largely unspecified) environmental factors.

Boas believed that historical research on the borrowing of customs (cultural diffusion) could identify a selective core of cultural ideas that determined which customs would be borrowed and which rejected, and that understanding this core should be high on the agenda for future anthropological research. His students sought to achieve this goal through culture and personality studies, but in doing so

they engaged in speculations—including psychoanalytic ones—he would not endorse. In the last book he edited, *General Anthropology* (1938), Boas included chapters by Sapir, Mead, and Benedict, but none on culture and personality, though the field was developing rapidly at the time (Stocking, 1992).

There is no doubt that Boas had a phenomenological side based on neo-Kantian philosophy that was expressed in his teaching and greatly influenced his students. From a contemporary perspective, he did not consistently distinguish between the “cultural” and the “mental”; rather, he saw them as fused. Stocking (1992, p. 312) points out that as late as 1907, Boas divided the whole discipline of anthropology into two parts, “biological anthropology” and “psychological anthropology,” apparently intending the latter title to designate what we now call “cultural anthropology.” This seems also to be the case with *The Mind of Primitive Man*, his magnum opus of 1911, in which “mind” refers to both cultural and mental phenomena.

In attempting to understand Boas as an ancestor of cultural psychology, we have to begin with his goal of falsifying the anthropological theories that divided the human species into hereditary racial types determining each individual’s bodily form, mental characteristics, and behavior, measurable through the cephalic index (the cranial height:width ratio). Boas focused first on the cephalic index itself: If one could demonstrate that it was highly variable within a population, as well as variable across generations raised under differing environmental conditions (when parents moved from rural to urban areas or from Europe to America), then the fixity of racial types was called into question and with it, the genetic determination of mental characteristics and behavior. Boas (1912) left no doubt, however, that his demonstrations of plasticity in physical growth implied that mental and behavioral attributes also varied in accordance with “social and geographical” factors. His strategy was to undermine racial formalism with a statistical approach to bodily characteristics, but this was only the first step.

In other works, Boas showed that the Native American languages and cultures exhibit qualities of order, complexity, and historical change incompatible with their characterization as “primitive” in older anthropological formulations, particularly those of an evolutionary

cast. Here, again, he focused on qualities that could be empirically assessed (though not quantitatively measured) to challenge theories of Western superiority with indisputable evidence. If it could be shown, for example, that the Native American languages were not deficient in their sound systems (phonology) compared to Western languages, but just different, and that the apparent deficiency was in the method used by early linguistic investigators (Boas, 1889), then the notion of Native American inferiority was undermined. But whereas the linguistic evidence showed the Native Americans to be *mentally capable* of speaking and transmitting a language equivalent in complexity and order to Western languages, it did not address directly the question of their other mental—as distinct from cultural—characteristics. Indeed, this is a question that Boas did not address himself—possibly because he could see no answer that would satisfy his radical empiricist scruples—but left to his students.

The lack of differentiation between the cultural and the mental in American social science discourse came to an end in 1917, when W. I. Thomas (the Chicago sociologist, later a collaborator of Sapir) and Florian Znaniecki published the first volume of their classic *The Polish Peasant in Europe and America* (1917/1927), with its introduction distinguishing between (social) “values” and (personal) “attitudes.” That same year, within the circle of Boasian anthropology, A. L. Kroeber, who had been Boas’s first student at Columbia, published “The Superorganic” in *American Anthropologist*, arguing that culture was in a realm of its own and not reducible to psychology or biology, and Sapir (1917) published a rejoinder, “Do We Need a Superorganic?” This debate—anticipated by the French sociologist Émile Durkheim’s (1895/1982) argument that society was *sui generis*, and that social facts were distinct from, and not reducible to, psychological facts—made it virtually impossible for social scientists to presume that a distinction between cultural and mental phenomena was unnecessary. The two realms might be related—in which case, how?—or unrelated—in which case, why?—but the problem was now unavoidable. This brings us to the contributions of Edward Sapir.

Sapir received his PhD with Boas at Columbia in 1909, and went on to become a founder of anthropological linguistics and a leading re-

searcher on Native American languages, before turning his attention to the study of culture and personality. In 1921 he published an influential book for the general public, *Language: An Introduction to the Study of Speech*. Sapir taught at the University of Chicago from 1925 to 1931 and thereafter at Yale. At both institutions he lectured on the psychology of culture—indeed, his Chicago course in 1926 was probably the first on this subject at an American university—but his planned book on that topic was not completed at the time of his death in 1939. More than 50 years later, students' lecture notes were compiled, and a book, *The Psychology of Culture*, edited by Judith Irvine, was published in 1993. (Some of his influential essays on culture and personality had been reprinted earlier in David Mandelbaum's [1949] *Selected Writings of Edward Sapir*.) Sapir also exerted an influence on behalf of culture and personality studies at the National Research Council, and at conferences sponsored by the Rockefeller Foundation and the Social Science Research Council. In these forums and organizations, he worked with and influenced younger anthropologists, such as A. Irving Hallowell and Clyde Kluckhohn, and other social scientists, such as Harold Lasswell, John Dollard, and W. I. Thomas. Sapir was widely admired as an intellectual leader and a fascinating lecturer. Thus, with relatively few publications on the subject, Sapir became known as the leading theoretical influence in culture and personality studies. The distinctive nature of this influence on Hallowell, Kluckhohn, and their students is of particular relevance here.

Sapir's model of culture and psychology was shaped not only by his training with Boas and his experience as an investigator of Native American languages but also by his friendship with the psychiatrist and psychoanalyst Harry Stack Sullivan, dating from 1926 (Darnell, 1990; Perry, 1982). Sapir incorporated Sullivan's (1947) theory of interpersonal relations (as the source of order and disorder in the mental development of the individual) in his own conception of culturally organized interpersonal relations as the source of meanings for individuals raised in a particular symbolic environment. In other words, children learn culture-specific symbols through their interpersonal experience, itself shaped by cultural conventions. The focus on the individual in Sullivan's psychiatric account was compatible with Boas's focus on the development of the in-

dividual human organism and with Sapir's own work with linguistic informants. Cultural meanings were transmitted from one individual to another through symbolic communication in interpersonal relations; the meanings, according to Sapir, had no life apart from the individuals who communicated them.

This last proposition represented a theoretical break with Kroeber's (1917) "superorganic" view of culture, which Sapir considered a reification (i.e., a form of what Merton would later call "misplaced concreteness"), and with other attempts to define anthropology as an academic discipline that owed little or nothing to psychology. The culture and personality movement initiated by Sapir, Mead, and Benedict attempted to counter the stronger current of disciplinary separateness that characterized the social sciences as they strove to establish themselves at universities in the first half of the 20th century.

The boundaries of Sapir's psychology of culture were marked by his disagreements with colleagues in the culture and personality movement, particularly Ruth Benedict and John Dollard. In his lectures on the psychology of culture at Yale, 1934–1937, Sapir made the following statements:

The term "cultural psychology" is ambiguous, and there has been much confusion between two types of psychological analysis of social behavior. The one is a statement of the general tendencies or traits characterizing a culture, such as the pattern of self-help in our culture; [as we have pointed out,] different cultures do have certain delineating factors, [including attitudes and] psychological standards about emotional expression. The other is a statement of certain kinds of actual behavior, [by actual individuals] related to these cultural patterns. [In other words, it is a statement of] the individual's psychology and the problem of individual adjustment [to a cultural setting.] . . .

[If the idea of a cultural psychology is so tangled, ought we to speak of such a thing at all? In a sense perhaps we ought not. Strictly speaking,] culture, in itself, has no psychology; only individuals [have a psychology.

On the cultural plane] there is only [what I call] the "as-if psychology." That is to say, there is a psychological standard in each culture as to how much emotion is to be expressed, and so on. This is the as-if psychology, which belongs to the culture itself, not with the individual personality. . . .

Ruth Benedict's book, *Patterns of Culture*, is a brilliant exposition of as-if psychology, but with confusion about the distinction made here. She is

not clear on the distinction between the as-if psychology she is discussing and the psychology of the individual. A culture cannot be paranoid. . . . You have to know the individual before you know what the baggage of his culture means to him.

In itself, culture has no psychology. It is [just] a low-toned series of rituals, a rubber stamping waiting to be given meaning by you. (1993, pp. 182–183)

This position reflected a breach between Sapir and Benedict, who had previously been close as friends and in their approach to the study of culture and personality. And since Margaret Mead adopted (or at least defended) Benedict's position, it also represented a split among the pioneers of the culture and personality movement. In my view, several of the younger anthropological researchers in that movement (e.g., Hallowell, Kluckhohn, Cora DuBois, and John Whiting, joined later by Beatrice Whiting and the students of Hallowell's students) followed Sapir on this issue. Benedict and Mead had little support among anthropologists altogether. But *Patterns of Culture*, published in 1934, became one of the best-selling social science books of all time, as did Mead's books, making Mead and Benedict the most famous American anthropologists of the century—not only in the 1930s but for decades thereafter, when their books were required reading at American colleges. Sapir's views, on the other hand, were delivered only to a classroom of Yale graduate students and to certain scholars who attended interdisciplinary conferences. For many within anthropology, and almost everyone outside it, culture and personality research was seen as representing Benedict's as-if psychology, not Sapir's critique and his more complex cultural psychology.

Sapir's disagreement with John Dollard was over other issues. The two had met in the late 1920s at the University of Chicago, where Dollard was a graduate student in sociology and Sapir, a senior professor of anthropology; their common interest was psychoanalysis. After finishing his doctorate, Dollard spent a year in training at the Berlin Psychoanalytic Institute and was brought to Yale by Sapir in 1931. At Yale, Dollard moved away from his mentor and joined an interdisciplinary group of psychologists and other social scientists exploring ways of testing Freudian theory through rigorous experiments, and applying the “learning

theory” of Clark L. Hull (later called “behavior theory” and based on drive-reduction experiments with animals) to human personality development and psychotherapy (Dollard, Doob, Miller, Mowrer, & Sears, 1938; Miller & Dollard, 1941; Dollard & Miller, 1949). (John W. M. Whiting and Allison Davis worked with Dollard during this period.) This type of social science, with its formal experiments, quantitative evidence, and reductionism, was anathema to Sapir, who saw his psychology of culture as exploring the complex symbolic worlds of human cultures through naturalistic methods used in ethnographic, linguistic, and clinical-psychiatric research.

Sapir was too much of an empirical scientist to accept the casual psychologizing of Benedict's ethnographic portraiture but also too much the humanist to accept the scientism of Dollard and the Yale learning theorists. I believe he was right on both counts, but Sapir faced insuperable obstacles in translating his sound ideas about cultural psychology into a research program: There were no relevant precedents in Boas's work, in ethnography or in his own linguistic research; his conception of the individual was drawn from psychiatry (Sullivan), which was itself struggling to find satisfactory methods of research; he never conducted psychological or psychocultural research himself and had no students who did during his life, which rapidly came to an end when he was 57.

Sapir's vision of a cultural psychology gave some substance and direction to Boas's general ideas about plasticity in human mental development. Having followed Boas in seeing the individual as the locus of culture, Sapir turned away from the statistical approach Boas had used to analyze the distribution of individual characteristics in a population, but without proposing a clear alternative. Like the cultural and personality movement he helped bring into being, Sapir's cultural psychology was a promising theoretical framework—focused on interpersonal experience as the basis for the individual's acquisition of cultural meanings—but it lacked a practical prescription for research. Nevertheless, the problems Sapir faced in his painful disagreements with Benedict and Dollard foreshadowed issues that remain critical in cultural psychology: the distinction between normative and idiosyncratic versions of culture (and their location) and the question of

how to assess or measure psychologically salient cultural ideas.

Sapir left a long list of publications on linguistics but only six articles on culture and personality and the unpublished lectures that were to have become his book on the psychology of culture. Had he lived longer, the book would have been published and it would no doubt have inspired others to conduct research on cultural psychology. In fact, A. Irving Hallowell (1892–1974) and Clyde Kluckhohn (1905–1960) had worked with Sapir in interdisciplinary seminars and had already been inspired to do field research during the 1930s and thereafter. Their studies and theoretical ideas are described in the following sections.

INDIVIDUAL VARIATION IN CULTURAL CONTEXT: HALLOWELL AND KLUCKHOHN

Most of Sapir's students at Yale became linguistic anthropologists; others became cultural anthropologists not concerned with psychology (David Mandelbaum) or psychological anthropologists more closely associated with Dollard and his methods (John and Beatrice Whiting). But Hallowell and Kluckhohn, though trained at the University of Pennsylvania and Harvard, respectively, were specialists in Native American cultures (Ojibwa and Navajo, respectively) who allied themselves with Sapir during the 1930s and sought to implement his ideas in their research.

Hallowell, as a student of the Boasian anthropologist Frank Speck at the University of Pennsylvania, had attended Franz Boas's seminar at Columbia (with Ruth Benedict) in 1922, and studied also with Alexander Goldenweiser, an early student of Boas, who was interested in psychoanalysis. By 1931, when Sapir led meetings on psychology and anthropology for the National Research Council, he picked Hallowell to be *rapporteur*. They worked closely during this period.

Kluckhohn, who had studied at Harvard and Oxford in the late 1920s, visited Sapir in New Haven weekly during the year 1936–1937 for lessons in the Navajo language (Stocking, personal communication, 2005). His writings at that time and later show him to be an admirer and follower of Sapir.

Both Hallowell and Kluckhohn developed working relationships with personality

psychologists—the former with Bruno Klopfer, the Rorschach analyst, and the latter with Henry A. Murray, coinventor of the Thematic Apperception Test—and wrote articles during the 1930s arguing and illustrating Sapir's points that culture should be conceptually distinguished from the individual psyche, that cultural patterns can be realized only in individual behavior, and that individual behavior (informed by culture) varies widely within a community or population.

In 1938 Hallowell published the article "Fear and Anxiety as Cultural and Individual Variables in a Primitive Society" in the *Journal of Social Psychology* (reprinted in 1955 as Chapter 13 of *Culture and Experience*). In it Hallowell used ethnographic evidence from his Ojibwa field studies to make the case against confusing personal adherence to conventional standards of thought and feeling with personal psychopathology.

Once we relegate commonly motivated fears to their proper frame of reference—cultural tradition—a fundamental etiological distinction can be made between fears of this category and those which arise in individuals from conditions primarily relevant to the circumstances of their own personal history. The *genuine* neurotic, in addition to sharing the culturally constituted fears of his fellows, as Horney says, "has fears which in quantity or quality deviate from those of the cultural pattern." Any comparison, then, between the fears and defenses of such individuals and the culturally constituted fears and institutionalized defenses of whole human societies is not only superficial, it is actually misleading, since no account is taken of differences in etiological factors. . . . To seriously maintain that the culturally constituted fears and defenses of primitive peoples are evidence of "cultural neuroses" which are of the same order as the neurosis of individuals in Western civilization, is just such a fallacy. Manifest surface analogies are compared whereas the underlying differences in the dynamic factors that produced them are ignored. (1955, p. 259; italics in original)

Although Ruth Benedict is not mentioned in the article, no reader in 1938 could miss the implied rebuke to her claim in *Patterns of Culture* (1934) that "culture is personality writ large" and her characterization of the Kwakiutl and Dobuan peoples in terms derived from psychopathology. Hallowell's quotation from the neo-Freudian psychoanalyst Karen Horney and

his citation in a footnote of a personal communication with Harry Stack Sullivan, leave no doubt that he was articulating and defending Sapir's position against that of Benedict.

Hallowell's terms "institutionalized defenses" and "culturally constituted fears" pointed to a more complex and promising understanding of person-culture interactions than is usually attributed to the culture and personality studies of the 1930s and 1940s. Except for a small group of specialists, however, the Benedict book—together with the books of Margaret Mead and Geoffrey Gorer (Gorer & Rickman, 1949)—overshadowed Hallowell and Sapir as the image of culture and personality theory and research for decades to come. Despite the respect he received as a North American Indian specialist, and his election to the presidency of the American Anthropological Association in 1949, Hallowell was only "discovered" as a theorist after the publication in 1955 of his *Culture and Experience*, in which many of his earlier essays were reprinted.

Kluckhohn also published an article in 1938 that made the point of differentiating between the individual and cultural forms. His article "Participation in Ceremonials in a Navaho Community," published in *American Anthropologist*, focused not on mental states and processes but on individual behavior: specifically, religious behavior. By counting the number of times individuals in a particular community performed a certain ceremonial activity, it was possible to move beyond generalized statements such as "the Navaho are a ceremonial people." The reported frequency of their religious acts would provide a more accurate description of Navajo ceremonialism. Kluckhohn's approach was based on the assumption that customary practices attributed to an entire community are actually variable among them, as Sapir had argued, but his quantitative method resembled sociology or psychology rather than linguistics:

Now our problem may be phrased as follows: To what extent does an inductive analysis of the behaviors of the individuals making up a particular Navaho group support the generalization that a preferred Navaho mode of reacting is ceremonial? (Kluckhohn, 1938, p. 360)

In short, the evidence which has been presented seems to create a strong presumption in favor of the hypothesis that ceremonials are a focal point of the actions of this Navaho society (p. 368)

Thus, Kluckhohn was implicitly presenting to anthropologists a radical methodological proposal, namely, that a crucial step in assessing the psychological salience of a discretionary or optional, though culturally organized, activity is to observe and record its frequency in a particular community. He also advocated assessing the economic costs of ceremonies and the amount of time spent doing them, as well as repeating these measurements over time to discover whether participation in ceremonials was increasing or decreasing. In other words, to avoid speculation about the "preferred mode of reaction" of a people, the anthropologist must measure individuals' reactions in observable situations and reportable activities in the aggregate. Kluckhohn offered this empirical and frankly reductive approach as necessary (though not sufficient) for psychocultural understanding, and, as with Hallowell's article, the implicit contrast with Benedict's *Patterns of Culture* could not have been sharper and would not have been missed by readers in 1938. Kluckhohn and Hallowell were both attempting to define the terms of a cultural psychology based on Sapir's critique of Benedict's approach as "as-if psychology."

However, behaviorist Kluckhohn's approach in that 1938 article also embraced two cardinal features of American anthropology (then and now): ethnographic knowledge and the concept of culture. The article on Navajo ceremonial participation, though focused on the counting of activities and behaviors, was framed—and made possible—by Kluckhohn's ethnographic knowledge of Navajo ceremonials and their contexts in Navajo culture and social life. And the following year, Kluckhohn (1939) published an article on the acquisition of culture by individuals in which he coined the term *culturization* ("an admittedly horrid word") as a counterpart to *socialization*, as used by sociologists and social psychologists.

The 1939 article presents Kluckhohn's recommendations for conducting research on a process that Sapir had, in his lectures, recognized as crucial to the psychology of culture. Kluckhohn's emphasis, however, was on the "empirical method" to be used, and on his argument that "if we are to deal with any problem (such as that of the acquisition of culture by individuals) in a way that is reducible to actual human behaviors, generalizations must be given a quantitative basis" (1939, p. 103). (Sapir, though emphasizing individual variabil-

ity in a population, would not have agreed that the acquisition of culture is reducible to behaviors; in any event, Sapir's focus was on the mental processes of "the culture-acquiring child" rather than the behavior of children and their parents.) Kluckhohn presented the topical outline and methods of his own study of Navajo children and his systematic sampling procedures, anticipating in many details the six cultures study of Whiting et al. (1966) 15 years later. He accused Malinowski and others of representing communities as a whole through contextualized "anecdotes" concerning their typical behavior, while ignoring individual variations. Benedict is not mentioned, though the criticisms obviously apply to her work as well. But Kluckhohn does not address in this article the question of what comprises the culture that is being acquired.

KLUCKHOHN'S SEMIOTIC VIEW OF CULTURE

Kluckhohn spent much of his subsequent career developing and refining the culture concept. Although he urged anthropologists to ground their descriptive statements about behavior in quantifiable observations, he had not abandoned Sapir's notions of cultural meanings and patterns. In 1945, he and W. H. Kelly published an article, "The Concept of Culture," in the form of a Socratic dialogue between an anthropologist and his colleagues and companions. The dialogue format enabled them to display a variety of viewpoints about culture, but Kluckhohn's preferred position emerged quite clearly: Culture is a historically created design or blueprint for living; it consists of both signs and symbols organized as patterns of and for behavior. This formulation is remarkably close in its metaphors as well as underlying ideas to the influential conception of culture for which Clifford Geertz (who was a student of Kluckhohn) has been known since the publication of his book, *The Interpretation of Cultures*, in 1973.

The following quotations from the Kluckhohn and Kelly dialogue indicate key features of the culture concept for which they are arguing.

Culture is not, strictly speaking, the visible act, the speech, or the product of these things. It is a *way* of thinking, feeling, believing. It is the knowledge stored up (in memories of men, in books and ob-

jects) for future use—patterns for doing certain things in certain ways, not the doing of them. (Kluckhohn, 1962, p. 25, italics in original)

The conception of one single, unchanging "human nature" is a reassuring fiction of folklore. When it comes to details, there are "human natures." (p. 36)

The notion of defining culture, in a descriptive sense, as a set of blueprints for action (including feeling, of course) is very attractive. And it is probably sound . . . (p. 53)

By "culture" we mean all those historically created designs for living, explicit and implicit, rational, irrational, and nonrational, that exist at any given time as potential guides for the behavior of men (p. 54) *and that tend to be shared by all or specially designated members of a group.* (p. 56, italics in original)

A culture is made up of overt, patterned ways of behaving, feeling, and reacting. But it also includes a characteristic set of unstated premises or hypotheses that vary greatly in different societies. (p. 58)

A language is not merely an instrument for communication and rousing the emotions. Every language is also a device for categorizing experience. (p. 59)

Social life among humans never occurs without a system of "conventional understandings" that are transmitted more or less intact from generation to generation. (p. 67)

Every culture is also a structure of expectancies. If we know a culture, we know what various classes of individuals within it expect from each other—and from outsiders of various categories. We know what types of activity are held to be inherently gratifying. (p. 69)

Thus, Kluckhohn's concept of culture was articulated in 1945 as a set of conventional, historically derived ideas that influence behavior, feeling, and thinking in a particular human group, a set of blueprints that shape interpersonal communication and expectancies, as well as other activities. Culture in this concept is both cognitive (knowledge) and normative (guiding action). It is not to be confused with behavior or artifacts produced under cultural influence. There is no suggestion that it could be reduced to quantifiable form.

This concept, which I would call "semiotic," is consistent with the concept of Sapir that in-

spired it and that of Geertz that followed later, though Kluckhohn was far more concerned than either of them to connect it to the interests of psychologists, biologists, and policymakers. In this regard, it is noteworthy that Sapir's proposed cultural psychology was based on clinical psychiatry as he had learned it through Harry Stack Sullivan, not on academic psychology. Kluckhohn, on the other hand, when he published the 1945 article, was already working with two academic psychologists (Henry A. Murray and Gordon Allport) and a sociologist (Talcott Parsons) in founding the Harvard Department of Social Relations, and he had written an article on culture and personality with the psychologist O. H. Mowrer (Kluckhohn & Mowrer, 1944). He did not reject their methods and approaches, but tried to relate his approach to theirs. From Kluckhohn's point of view, Sapir's opening to clinical psychiatry, which failed to address the question, for example, of the representativeness of individual cases, was not adequate for anthropology as a social science.

As for Geertz, however much Kluckhohn's 1945 concept of culture was compatible with his viewpoint (initially developed when he was a graduate student in the Social Relations Department at Harvard), he found much to disagree with by the 1950s. Kluckhohn's published monograph with A. L. Kroeber on definitions of culture (Kroeber & Kluckhohn, 1952) retreated somewhat from the purely ideational concept of culture, seeking an ecumenical consensus definition that admitted products and practices under the cultural umbrella. In response, Geertz (2000) became determined to "shrink" the culture concept by his own work. Furthermore, Kluckhohn continued to insist on the importance of human cultural universals rooted in biological and situational constraints and to speculate on what the universals might be (Kluckhohn, 1953), whereas Geertz (1973, p. 29) developed the viewpoint that "it's culture all the way down," that cultural inquiry can reveal only the patterns of a particular symbolic system, and only if it is not burdened by the assumption that all systems, sharing universal constraints, must be comparable with another.

Kluckhohn (personal communication, 1953–1954) saw Sapir's work on the phoneme—a universal biosocial category permitting language-specific variations—as the model for

conceptualizing culture in general, and in this sense his semiotic viewpoint resembled that of the linguist Kenneth Pike (1954), who extended the linguistic division between phonemic and phonetic analysis to the description of particular cultures in the *emic-etic* distinction. But Geertz, approaching culture through phenomenological philosophy, hermeneutics, and literary criticism, apparently saw this as a form of scientism that led away from the deeper understanding of particular cultures. As of this writing, Geertz has not dealt directly with the psychology of culture (LeVine, 2005).

Although it is not explicitly stated in Kluckhohn's posthumously published book of essays, *Culture and Behavior* (1962), which was incomplete when he died, it seems clear that the title represents his recommendations for a cultural psychology: Culture is to be studied as a set of ideas—knowledge and norms—constituting a partly shared symbolic system that the anthropologist describes holistically. The behavior of individuals in a particular community is to be recorded and aggregated to permit quantitative description. The investigator then searches for correspondences between cultural ideas and behavioral profiles or distributions (e.g., in the central tendencies of behavior in two communities of different cultures), predicting behavioral tendencies from cultural differences. This seems to have been Kluckhohn's preferred cultural psychology at the time of his death in 1960 at the age of 55. (He was also, as mentioned, searching for the universals in which the cultural variations in behavior were grounded.) Of course, this method had a precedent in Émile Durkheim's (1895/1951) *Suicide*, which Alex Inkeles (1959) referred to as correlating a state and a rate, and it was used in many comparative studies throughout the 20th century, including those of recent cultural psychology (e.g., Markus & Kitayama, 1991).

Kluckhohn may not have acknowledged the Durkheim precedent, but his unfinished work represents a pioneering mid-20th-century effort to realize Sapir's dream of a cultural psychology—not in the way Sapir imagined it, but by connecting ethnography with empirical (and quantitative) psychology. The book of readings Kluckhohn edited with Murray in 1948, *Personality in Nature, Culture and Society*, represented this interdisciplinary connection in a sophisticated and mature phase that

was often forgotten in subsequent criticisms of the culture and personality movement. Working in parallel to Kluckhohn, Hallowell mounted another pioneering effort to extend Sapir's ideas and translate them into a research program.

HALLOWELL'S CONCEPT OF THE SELF

Most of Hallowell's psychocultural papers were reprinted in his 1955 book *Culture and Experience* (which is still in print), which includes his articles on Rorschach testing among the Ojibwa, his presidential address to the American Anthropological Association on personality and human evolution, and his new thinking on the self in culture. The latter seems particularly important as a precursor to contemporary cultural psychology, though it was not appreciated in anthropology for perhaps another two decades.

Hallowell's lengthy article, "The Self and Its Behavioral Environment," is divided into two chapters in the book, one with the original title and the other titled "The Ojibwa Self and Its Behavioral Environment," wherein he outlines and illustrates his comparative framework for studying the self cross-culturally. Far from claiming originality, Hallowell (who was a pioneering historian of anthropology) indicates his predecessors in exploring the self, including Ernst Cassirer in philosophy; William James, James Mark Baldwin, and Gardner Murphy in psychology; George Herbert Mead and C. H. Cooley in sociology; and Marcel Mauss (1938) and Dorothy Lee (1950) in anthropology. His framework is original, however, in several respects.

Hallowell begins to present his assumptions and hypotheses by emphasizing that the self-awareness of humans is not only a "social product" but also "culturally constituted."

If it is possible to view the self as culturally constituted and known to the individual in the same frame of reference as we view the culturally constituted world in which the individual must act, this preliminary step may enable us to apprehend with greater clarity both the essential role of culture in relation to a generic human attribute and to define with more precision some of the constant and variable factors that structuralize the psychological field of behavior for the individual in different societies. (Hallowell, 1955, p. 81)

For the acquisition and use of a particular language, the specific content that is given to an articulated world of objects that is built up *pari passu* with self-awareness, and the integration of personal experience with a concept of the nature of the self as traditionally viewed, are among the necessary conditions that make possible the emergence and functioning of human awareness. . . . At the same time, such cultural constituents give various colorings to this unique psychological attribute of man. (p. 82)

Culture may be said to play a constitutive role in the psychological adjustment of the individual to his world. (p. 89)

Hallowell makes clear in this chapter that the culturally constituted self of which he writes is not simply a collective representation or an aspect of a disembodied culture but is essential to and part of individual psychodynamics. He also proposes a set of universal dimensions for the mental contents of the self: self-orientation, object orientation, spatiotemporal orientation, motivational orientation, and normative orientation. He argues the plausibility of these hypothesized orientations with ethnographic data (especially his own from the Ojibwa) and quotations from developmental psychologists and philosophers whose observations have led them to believe they are universal.

The orientations, as Hallowell expounds them, are what Kluckhohn at about the same time called "universal categories of culture"—"the invariant points of reference" (1953, p. 522)—within which cultural variability occurs. Thus, the normative orientation means that a moral order of some kind is universal in human societies; it does not mean that any particular morality is common to more than members of a particular community. Hallowell's orientations are psychological parameters or dimensions along which culturally constituted selves vary widely. This way of reconciling the ethnographers' perceptions of cultural variation with the assumption of species-wide, biologically grounded human attributes—whether or not it reflects the influence of Sapir and his concept of the phoneme—seemed to Hallowell and Kluckhohn to be as the foundation for research into cultural psychology in the 1950s.

Hallowell's conceptual suggestions for cultural psychology did not end with the five orientations of the self; the essays reprinted in

Culture and Experience also pointed to a cultural psychodynamic. When Hallowell referred to “culturally constituted fears and institutionalized defenses” in the passage quoted earlier from his 1938 article (Chapter 13 in *Culture and Experience*), his primary goal was to distinguish such fears and defenses from their phenotypically similar symptoms in the psychiatric diagnosis of mentally ill individuals. Thus, in a behavioral environment constituted according to Ojibwa cultural standards, believing in witchcraft and sorcery is conventional and not to be equated with the phobic or paranoid beliefs of mentally ill patients, who stand out as different among the Berens River Ojibwa as they do elsewhere. But how are we to understand the nonpathological belief in witchcraft and sorcery? In Chapter 14 (originally published in 1941), he asserts that “the whole magico-religious apparatus of the Salteaux [Ojibwa] is a complex anxiety-reducing device” (1955, p. 276). Traditional beliefs about disease arouse the anxieties of the ordinary person, but customary therapeutic practices operate symbolically to reduce them, in a theoretical model analogous to that of the psychodynamics of symptom formation in psychoanalysis.

Later, Melford E. Spiro (1961, 1965) explicated the concept of “culturally constituted defenses” in theoretical terms and with ethnographic examples, advancing the cultural psychodynamics implicit in Hallowell’s writings. Spiro (1961) wrote that cultural practices can be functional for the individual, whose forbidden impulses are allowed disguised expression that might otherwise lead to psychosis, and for the society, which tames or contains its members’ potential disorderly behavior. Thus, the description and analysis of culturally constituted defenses become central to the understanding of society, culture, and personality in terms of a psychosocial functionalism, combining Freudian psychodynamics with the social-structural functionalism of Talcott Parsons (homeostatic models of psychic and societal equilibrium). Obeyesekere (1990), who sees Kardiner’s works (1939, 1945) as originating the concept of culturally constituted defenses in his formulations concerning “projective systems,” critically reviews Spiro’s use of the concept in the latter’s analysis of Burmese Buddhist monks, finding it unnecessary to assume, as Spiro does, that the defenses substitute for psychoses. Obeyesekere’s (1981) own research in

Sri Lanka exemplifies an approach in which defenses drawing on religious imagery play a crucial role in the psychodynamics of religious specialists without making that assumption.

Hallowell therefore laid the conceptual foundation for not only the ethnographic and psychological study of the self in diverse cultures but also the future study of cultural psychodynamics, with culturally constituted defenses as its central concept. If that possibility has remained largely unrealized, it is probably due to the lack of an empirical research program on which psychological anthropologists after Hallowell could agree. This in turn seems to be a function of (1) doubts about the cross-cultural validity of projective tests and other personality assessment methods that arose in psychology (e.g., Lindzey, 1961) during the 1960s; (2) unresolved issues regarding cultural particularism versus Freudian universalism and clinical versus statistical approaches among the psychological anthropologists who might have been expected to construct such a program; and (3) the unstated recognition in anthropology that collecting valid data about culturally constituted defenses without the use of personality tests is extremely difficult for a foreign anthropologist to do.

Whatever the research after 1960 that followed the writings of Kluckhohn and Hallowell, it is now possible to appreciate their contributions to the foundations of cultural psychology. They elaborated Sapir’s distinction between culture and the individual. They implemented that distinction in their studies of the Navajo and Ojibwa, respectively, explicitly following Boas in their use of samples and statistical methods. Kluckhohn revived attention to the concept of culture and suggested the ideational approach that eventually became dominant. Hallowell formulated the self as an object of ethnographic inquiry, and initiated interest in culturally constituted defenses as a key concept for the cultural study of psychodynamics.

ETHNOPSYCHOLOGY

In the late 20th century, many diverse strands of anthropological theory and research were seen as foundations of cultural psychology. For example, in the year 1973 alone, the following five books were published in the United States: *Socialization for Achievement: The Cultural Psychology of the Japanese* by George A.

DeVos, *The Anatomy of Dependence* (English translation) by Takeo Doi, *The Interpretation of Cultures* by Clifford Geertz, *Culture, Behavior and Personality: An Introduction to the Comparative Study of Psychosocial Adaptation* by Robert A. LeVine, and *Tahitians: Mind and Experience in the Society Islands* by Robert I. Levy. It would take another chapter to do justice to the analyses and evidence in all of these works, but several of them are particularly relevant to this chapter.

Ethnopsychology as a field of research was prominent in the anthropological literature during the 1970s and 1980s, and represents an important aspect of and problem for cultural psychology. An ethnopsychological account is a description of the psychological categories (i.e., concerning emotion, cognition, behavior, and development) indigenous to a particular language and culture. Ethnopsychological descriptions raise the questions of the extent to which those categories can be translated into Western psychological concepts, whether the latter provide a basis for understanding persons in non-Western contexts, and whether psychology as we know it is only of many culture-specific conceptualizations rather than a scientific theory of universal validity. At the same time, an ethnopsychological account calls attention to the issue of whether experience, individual and collective, can be adequately understood in terms of indigenous cultural categories alone or requires the assumption of universal mental processes for a satisfactory explanation. These are issues of fundamental import to cultural psychology.

Tahitians, by Robert I. Levy, who became an anthropologist after a career in clinical psychiatry, then did 26 months of field work in Tahiti, played an important role in bringing these issues to the fore and stimulating ethnopsychological research during the 1970s and later. His book elevated the standards for understanding psychological experience in a culture other than our own and stands as a model for such investigations 32 years after its publication. Levy did not use the word *ethnopsychology* in the book and did not classify his own work among previous studies in that field.

Ethnopsychology had been independently invented by various field-workers who encountered people in another culture using vernacular terms to describe and explain what we would call their mental processes or subjective experience. Many 20th-century ethnographers

assumed that the cultures of the world have diverse points of view on many phenomena, including thought, emotion, and personal development. Before the 1970s, most anthropologists did not use the term *ethnopsychology* or cite earlier studies of a similar sort. A good example is the 1959 article by Hildred Geertz, "The Vocabulary of Emotion: A Study of Javanese Socialization Processes." It seems that the earliest use of the term *ethnopsychology* as a body of knowledge equivalent to ethnobotany and other "ethnoscience" was in the 1950 (third) edition of *The Outline of Cultural Materials* by Murdock et al., the volume that provides the categories for the Human Relations Area Files as an archive of ethnographic data. The ethnographic monographs that took an ethnopsychological approach before *Tahitians* are George Devereux's (1961) *Mohave Ethnopsychiatry and Suicide* and Jean Briggs's (1970) *Never in Anger*.

Devereux's book is unfortunately flawed by a disorganized and opinionated presentation; the Mohave voice is there, but it is drowned out by lengthy commentaries. Briggs's *Never in Anger: Portrait of an Eskimo Family* is well known as an ethnographic masterpiece that generates psychocultural insights from a detailed account of the anthropologist's relationship with one family. But it was also a landmark in ethnopsychology, providing a glossary of emotion terms used in the text and a 55-page appendix explaining the meanings of these terms and the normative contexts that specify their use in everyday life. This was an exemplary, though circumscribed, demonstration of the ethnographic depth and microscopic attention needed to translate emotional experience from one culture to another.

Levy's *Tahitians* (1973) was another such demonstration, but on a larger canvas and with a broader set of goals. Levy sought to convey in convincing detail how Tahitian psychological concepts were collective and personal at the same time. He coined terms such as "shared privacy," which seems to embody a contradiction, that he judged were needed to frame a description of communication as inevitably social and psychological, conventional and idiosyncratic. This theoretical frame, derived in part from Gregory Bateson (to whom the book is dedicated), provides the structure for relating cultural symbols and personal experience through the communicative contexts of social interaction. A person-centered ethnography of

over 500 pages, it provides an unusually rich combination of ideational and behavioral material, a critical and self-critical questioning of descriptive generalizations, and meticulous attention to the justification of inferences concerning connections between observable behavior and subjective experience. It remains unsurpassed as an ethnopsychological description of a community, for at least five reasons:

1. Levy's ethnopsychology provides a contextual and pragmatic account rather than a formal taxonomy. Although a glossary of Tahitian psychological terms is included and their meanings are examined, their practical contexts and functions in Tahitian social life, and in the lives and actions of participants, are the focus rather than the cognitive relationships of the terms.

2. The historical situation is part of the ethnopsychological portrait. The Tahitians with whom Levy worked had lost most of the rituals and other aspects of public culture described in travelers' accounts from the 19th century, but some meanings lived on, in altered forms, in the sphere of interpersonal relations and the subjective experience of individuals. Levy's detailed historical documentation thus provides a dynamic dimension that is often missing in descriptive ethnopsychology.

3. The text of the study involves a gradual movement from the observable social surface of interpersonal relations to inferences about personal experience and psychodynamics at greater depth and abstraction. This movement embodies in ethnographic work the approach of a careful psychoanalytic clinician—without, however, requiring a prior commitment to psychoanalytic theory.

4. Levy's concepts of *hypocognized* and *hypercognized* feelings introduced the dimensions of psychological salience and awareness into ethnopsychological description, which can otherwise treat all terms as equally salient. This distinction is Levy's restrained and empiricist way of dealing with the issues of psychic censorship and repression that Freud (1900/1958, 1913/1958) introduced in *The Interpretation of Dreams* and applied to culture in the early chapters of *Totem and Taboo*. As Levy recognized, it moves ethnopsychology into the field of psychodynamic interpretation, requiring clinical investigation but gaining deeper illumination of social behavior.

5. The organization of experience in cultural representations and personality is deliberately included. Levy assumed that an understanding of Tahitians' experience could not end with a description of the lexicon in which their experience was encoded but had to include the ways ideas and behavior were organized, and disorganized, and the style that characterized their behavior. The characterization of organization in culture or personality involves another set of inferences that can reflect illusory correlations or at least systematic distortion—as Shweder and D'Andrade (1980) have warned—but which Levy was prepared to justify with empirical evidence from multiple sources.

Thus, *Tahitians* provides the lesson that ethnopsychology, however necessary as an instrument of cultural and psychological understanding, is insufficient without investigation of the communicative contexts, both personal and social, that give the lexicon of thought and feeling its meanings. He includes the results of clinical interviews designed to illustrate the various ways Tahitian categories of experience work out in individual lives. On the whole, however, Levy resists depth interpretations and perhaps leaves questions a reader might have about Tahitian personality unanswered; the implication is that they are unanswerable through the ethnographic research of an outsider.

As mentioned earlier, Geertz's *The Interpretation of Cultures* was also published in 1973. In his chapter on person, time, and conduct in Bali (originally published in 1966), Geertz said:

What we want and do not yet have is a developed method of describing and analyzing the meaningful structure of experience (. . . the experience of persons) as it is apprehended by representative members of a particular society at a particular point in time—in a word, a scientific phenomenology of culture. (1973, p. 364)

It is ironic that these words were reprinted during the same year that Robert Levy actually offered such a method in *Tahitians*. For psychological anthropologists, Levy's multifaceted work in Tahiti was an admired model, difficult to emulate; but for anthropologists outside of our subfield it was easier (and more in keeping with disciplinary orthodoxy) to expunge "psychologizing" even from the study of such

obviously mental contents as thought, emotion, and self-concepts.

But another book published (in its English translation) in 1973 pointed in a more promising direction. Takeo Doi's *The Anatomy of Dependence* presented an analysis of Japanese relationships in home, work, and therapeutic settings through the extended description of a single Japanese vernacular term, *amae*. Doi is a Japanese psychiatrist partly trained in the United States, where he was exposed to psychoanalysis and American culture before beginning clinical work in Japan. Like Levy, he had years of clinical experience and a healthy skepticism about orthodox Freudian theory before embarking on cultural study. Unlike Levy, however, Doi was explicating his own culture, albeit in comparison with American culture as he experienced it, and interpreting the behavior of individuals from the same cultural background as himself. His insights into normal and pathological development in Japan are deep and illuminating, and they are convincing in a way that is hard (though not impossible) for an outsider to achieve. This suggests an alternative to the difficult challenge of matching Levy's masterful accomplishment in *Tahitians*, namely, turning the kind of ethnopsychology it exemplifies into a research program by scholars of diverse backgrounds instead of a method in which Westerners describe, translate, and interpret the terms of non-Western experience.

Doi (1962, 1973) translated the Japanese term *amae* as "to presume upon the benevolence of others" and argued for its pervasiveness in Japanese interpersonal relations (including formal bureaucratic relationships), its individual origins in a culture-specific pattern of mother-child interactions, and its involvement in forms of neurosis occurring among the Japanese. His evidence is anecdotal but drawn from his clinical observations and his experience as a Japanese man. It has the authority of the insider's judgment combined with Doi's awareness of how the patterns he describes differ from those he experienced in the United States. He followed the first book with a second, *The Anatomy of Self* (Doi, 1986), which extends his ethnopsychological description of Japanese experience into the social world of typical individuals in Japan and also contains comparative observations. Doi's writings influenced others investigating psychological issues in Japan (e.g., Lebra, 1976, 1994; Schwalb &

Schwalb, 1996) and provided a powerful example of how culturally specific expectations concerning psychologically significant phenomena can be embedded in the verbal idioms of a particular language. Doi himself remains convinced that although the Japanese have their own way of thinking, feeling, and talking about themselves, their ways are but a particular version of universal aspects of human experience.

A number of subsequent ethnopsychological studies carried out in Oceania are presented in the books by White and Kirkpatrick (1985) and Lutz (1988); a thoughtful review by White appeared in 1992. Ethnopsychology forces us to confront the drastically different terms in which peoples of diverse cultures conceptualize their experience: They may locate emotions in parts of their bodies or in invisible spirits rather than in their conscious or unconscious selves, and in that sense it is fundamental to cultural psychology. Yet ethnopsychological research, though necessary to reconstruct the insider's experience, is only the first step toward understanding and explaining that experience.

EPISTEMOLOGICAL ISSUES IN PSYCHOLOGICAL ANTHROPOLOGY

I have long believed that the culture and personality movement of the period 1925–1960 generated new, important, and basically sound theoretical ideas but failed to achieve consensus on a research program, on methods to be used to test and elaborate the theory, or even on what body of knowledge it was attempting to construct through its research. Many of those issues remain unresolved. In this section I offer my own efforts to address these issues, particularly during the 1970s, as exemplifying this lack of resolution.

My view of the tasks of culture and personality research was based on Spiro's (1961) distinction between culture as *explanans* and culture as *explanandum* (i.e., culture as an explanatory factor in the analysis of personality and behavior, and individual motivation as explanatory in the analysis of culture). Spiro argued that anthropologists had focused on showing that culture helps account for cross-population variations in the distribution of psychological and behavioral characteristics (as in Kluckhohn's "culture and behavior"

model mentioned earlier), but tended to neglect the ways in which individual motivational factors influence cultural stability and change. Insofar as culture and personality interact with and mutually affect each other (as originally suggested by Thomas and Znaniecki in the introduction to the 1917 edition of their volumes, *The Polish Peasant in Europe and America*), both types of research and analysis were equally necessary. I accepted this imperative and explored it in my 1973 book, *Culture, Behavior and Personality*.

On the side of culture as an explanatory variable, I proposed a “population psychology” resembling population genetics, epidemiology, and other statistical sciences of populations to investigate specific cultural influences on behavioral/psychological variations across populations. This was not an original idea but seemed an obvious implication of earlier social research from Durkheim’s (1895/1951) study of suicide to the formulations of my teachers Gordon W. Allport (1954) and Alex Inkeles (1959), and I had already presented it myself in articles (LeVine, 1966, 1970). (Dan Sperber, in 1985, proposed an “epidemiology of representations.”)

As I envisioned this approach, variations across populations in phenotypic behaviors (i.e., behavioral indicators of individual emotional and cognitive dispositions) would be described in terms of their statistical distributions, then related to the cultural and institutional environments inhabited by the individuals of differing populations. This “culture and behavior” approach based on population studies often leaves an intervening “black box” of hypothesized dispositions that are only indirectly assessed through behavioral indicators and require deeper investigation to uncover the psychosocial processes that mediate the influence of culture and institutions on observable behaviors. The approach is also susceptible to the “ecological fallacy” in which covariations across populations are taken to be causally related, when they might be the results of historical accident or unmeasured determinants. Thus, the initial analysis of statistical distributions would have to lead to further research—clinical, developmental, and neurophysiological—designed to clarify what the mediating dispositions are and how they operate in the processes and contexts of social life.

On the other side—that of the psychological analysis of culture—I made a more innovative proposal that would prove far more controversial. When psychological factors are taken as underlying causes of a social process, as in all motivational theories, the need for valid measurement of those factors is even greater than when psychological factors are hypothesized as outcomes. But how are the deep psychological causes of cultural stability and change to be measured? For Spiro (1970), as for his teacher Hallowell, the answer was to be found in the Rorschach test. But I found not only great disagreement among psychologists about how to analyze Rorschach responses but also a powerful cross-cultural critique of projective techniques by Gardner Lindzey (1961) that had never been answered in subsequent research. In addition, collaborating with the social psychologist Donald T. Campbell (LeVine & Campbell, 1972) had acquainted me with the devastating critiques of personality tests and experimental assessment procedures that had created a validity crisis within personality and social psychology during the 1960s. As an anthropologist shopping for a means of assessing the psychological causes of cultural patterns, I was looking for something more valid than academic psychology seemed to offer.

Having completed my training at the Chicago Institute for Psychoanalysis in 1971, I tried to rethink cross-cultural personality measurement from an epistemological perspective on the clinical situation in psychoanalysis. I argued that, as a long-term series of observations free of the pressure to reach final diagnostic judgments, psychoanalysis offered methodological advantages over the shortcut procedures of projective tests and psychometric personality measurement, advantages that might generate more valid methods usable among the illiterate majority of humans. For this I was pilloried by some personality psychologists: The review of my book by H. J. Eysenck was titled “Commit It to the Flames.” Yet I knew that my concerns about validity were shared by many other psychologists concerned only with Western populations. Anthropologists as fieldworkers had a deep-seated aversion to imported rapid assessments that seemed not to capture what they saw in the field, but their criticisms (and mine) were not entirely alien to those of thoughtful social psychologists and psychometricians.

In the book, I made a number of tentative suggestions about how to adapt psychoanalytic clinical method to field situations, including the “bicultural collaboration” of an insider social scientist (who had acquired a particular culture in childhood) with the conventional anthropologist approaching that particular culture and its patterns of experience from the outside, using the tools of ethnography. Rather than specifying methods in advance, I recommended criteria for the development of methods in the field. Soon after the book was published, however, I embarked on a 2-year collaborative study of infant care among the Gusii of Kenya, and my primary attention has been on issues of early child development ever since (LeVine et al., 1994). Thus my project of constructing a new, psychoanalytically influenced, approach to personality assessment in diverse cultures was never brought to completion.

In the second edition of the book (LeVine, 1982), I added a chapter, “The Self in Culture,” that recognized the emergence during the previous decade of anthropological field studies focused on experience, to which I gave the label “person-centered ethnography”:

Taken together, these . . . tendencies comprise a new attack on subjective experience in other societies—its indigenous cultural constituents, its form and content in individual lives and its problematic role in the investigative relationship. This new attack operates without an explicit consensus on methods of data collection or comparative analysis. It is a development of and from the ethnographic tradition in anthropology: a person-centered ethnography, taking the individual perspective on culture and experience rather than that of a collective system or external observer. Standard ethnography produces a cultural description analogous to a map or aerial photograph of a community; person-centered ethnography tells us what it is like to live there—what features are salient to its inhabitants. Like other anthropological field workers, person-centered ethnographers often aspire to “thick description” (Geertz, 1973)—accounts of sufficient detail and diversity to reveal the meanings that lie behind behavior. This is a modest step toward generalization compared to cross-cultural hypothesis-testing, but it represents the conviction that greater ambitions cannot be fulfilled without data of better quality. (p. 293)

In the remainder of that chapter, I proposed an ethnographic approach to the self through

the narratives embedded in local conventions of interpersonal communication: conventions of face-to-face interaction, ritual, and autobiographical discourse that contain narratives of a culturally constituted self. Having retreated from a direct attempt to plumb the depths of personality, I found in the focus on self a way of uniting Hallowell’s cultural phenomenology with the psychoanalytic self psychology of Heinz Kohut (1971, 1977). By exploring continuities and discontinuities—repetitions and dialectical tensions—between cultural narratives of interaction and those of the imagination in a given community, it would be possible, I argued, to identify the culturally constituted representations of self (including defenses) characteristic of a local population. This approach remains to be elaborated in future work.

My approaches to the assessment of socially significant aspects of individual psychology, like those of many other anthropologists, have been to “complexify” its assessment, in contrast to the psychologist’s typical simplifying and reductive approach. In the aforementioned chapter, I made the following argument, which can serve as the conclusion of my work to date:

A major lesson from research in personality and social psychology of the past two decades is that there can be no psychological X-ray that bypasses contextual analysis, no way of tapping “pure” dispositional competence uninfluenced by the conditions surrounding its observable performance—any more than it is possible to speak without speaking a particular language. . . . Deprived of the illusion of “independent” and “direct” personality assessment, the psychological anthropologist has no choice but to ground psychological investigation in an ethnographic analysis of communicative contexts. (LeVine, 1982, p. 295)

CONCLUSIONS

This selective review of anthropological foundations of cultural psychology has taken a historical approach, revealing that American anthropologists between 1925 and 1975 concerned themselves with some of the basic topics of contemporary cultural psychology. Their formulations—on the nature of culture; the relationships of cultural ideas and practices to individual mental processes; the self-concept as culturally variable, culturally constituted de-

fenses; and the translation of indigenous psychological terminology—were grounded in ethnographic fieldwork with native North Americans, Pacific Islanders and other non-Western peoples. Their writings remain instructive, not only in terms of revealing the emergence and evolution of concepts and research agendas during the 20th century but also in terms of understanding earlier efforts to grapple with fundamental issues that continue to affect cultural psychology.

Edward Sapir, in the 1920s and 1930s, saw the need for a cultural psychology that studied the relationships between cultural symbols and the individual psyche, and he attempted to ground it in clinical psychiatry rather than in academic psychology, or any other discipline that took a statistical approach to individual variation. The culture and personality movement he cofounded did not achieve a consensus on this issue or on issues of universalism versus relativism and the use of psychological tests versus ethnographic and clinical approaches to capture the individual psyche as distinct from but influenced by culture. When the movement came to an end after 1950 and transformed itself into “psychological anthropology” (see LeVine, 2001), a consensus on these issues remained elusive, and though increasingly sophisticated theoretical and empirical studies followed, the field as a whole continues to have an exploratory and provisional character. We still struggle with problems of validity that need to be solved to translate Sapir’s dream of a cultural psychology into an effective interdisciplinary research program.

CHAPTER 3

Culture and Psychology

A History of the Study of Their Relationship

HARRY C. TRIANDIS

The history of the study of the relationship between culture and psychology has been presented in considerable detail by Jahoda (1993). Other histories have been published by Klineberg (1980) and Jahoda and Krewer (1997). Furthermore, Cole (1996) included much historical material in the first section of his *Cultural Psychology*. What follows is my integration of these publications, supplemented by personal observations, because I was somewhat involved in this history during the last half-century. I also try to assess the future of the relationship of culture and psychology by examining how historical trends in psychology have shaped current work and will shape future work in this field.

EARLY HISTORY

Students of psychological processes in antiquity and the Middle Ages usually contrasted the assumed universal psychological processes found in their location with “inferior” psychological processes found among “inferior” groups (Jahoda & Krewer, 1997). One exception was Herodotus (460–359 B.C.), who realized that people in all cultures are ethnocentric.

They see themselves as the centers of the world, and processes that are common in their location are “good,” whereas processes that are different are “bad.” Thucydides (about 455–395 B.C.) was a boy when he heard Herodotus recite from *The Histories* at the Olympic Games. He was so moved that he wept (Thucydides, 1934). Later when he wrote his *History of the Peloponnesian War*, Thucydides provided a surprisingly modern account of psychological processes. He argued that there were differences in the fertility of soils in ancient Greece, and humans gravitated toward the fertile soils. To hold these fertile soils people had to fight, so they developed war-like attributes. However, those who did not like fighting moved to the Athens area, because it was not fertile. As a result, a highly heterogeneous population comprising people from all over Greece settled in Athens. These people had different ways of perceiving the world, but because they did not like to fight they debated with considerable frequency to reach agreements. Democratic behavior patterns and institutions were generated as a result of these debates (Thucydides, 1934).

Thus, the ancient Greek historians had two insights: (1) People in all cultures are

ethnocentric, and (2) ecology leads to reciprocal relationships among personality, culture, and social institutions. This view emerged again in psychological anthropology (Whiting, 1973/1977, 1994) and in modern psychology (Berry, 1976, 2003; Cohen, 2001; Nisbett, 2003; Triandis, 1972).

Ethnocentrism is a universal human attribute (Herskovits, 1955; Triandis, 1990). It is inevitable because most people start life by knowing only their own culture, and see themselves as being located in the center of the world. Thus, for instance, the Ancient Greeks thought that the center of the earth was located in Delphi, and they even specified the exact spot, which they called the *omphalos*—meaning the belly button of the world. Everyplace to the east of Delphi was called East, and everyplace to the west of Delphi was called West. The Romans adopted this terminology, which then entered into the European languages, so that even today we talk about “the Middle East” and “the Far East,” as well as “the West.” The Ancient Assyrians, who wrote on the tablets now in the Pergamon Museum in Berlin, were quite explicit that they were the center of the world, and their king, Sargon II, was “King of the universe.” Herskovits (1955, p. 356) noted that “the ethnocentrism of nonliterate peoples . . . is manifest in many tribal names whose meaning in their respective languages signifies ‘human being.’” The Chinese called their country “the central kingdom.” In 1793 the Chinese Emperor Ch’ien Lung wrote to George III of England as follows: “We possess all things. I set no value on objects strange or ingenious, and have no use for your country’s manufactures” (Klineberg, 1980, p. 31).

Only people who are in touch with many cultures, as was the case with Herodotus, who visited about 30 cultures in all directions around Greece, see that ethnocentrism is due to ignorance. Vico (1744/1970) established an “axiom” that stated, “It is another property of the human mind, that whenever men can form an idea of distant and unknown things, they judge them by what is familiar and at hand” (p. 18). This, Vico pointed out, is an inexhaustible source of errors for judging other cultures.

A consequence of ethnocentrism is the perception of what goes on in “our culture” is “natural,” “normal,” and “correct,” whereas what goes on in other cultures is “unnatural,” “immoral,” and “incorrect” (Brewer & Camp-

bell, 1976). Ingroup customs are perceived as universally valid. Ingroup norms, role definitions, and values are “obviously correct.”

With very few exceptions up to about 1900, most studies of the relationship of culture and psychology were ethnocentric. Even in the 20th century, most psychologists thought that their discoveries were “universal laws” and “eternally valid.” This view became less and less acceptable as cultural psychology developed. In the 1970s, a few psychologists abandoned the universalistic view and after Markus and Kitayama (1991) published “Culture and Self,” universalism became a minority view.

During the Renaissance (15th and 16th centuries), the universality of psychological processes was assumed, but increasing diversity became apparent as trade and exploration resulted in diverse peoples’ meeting. Some writers, such as De Las Casas and Montaigne (Jahoda, 1993, p. 8), questioned the universality of moral principles and started a debate on universalism. But for most writers ethnocentrism was endemic. Also, it was assumed that cultures went through a linear evolution from “savage” to “civilized.” Vico (1744/1970) identified three stages of the evolution of cultures—the divine, the heroic, and the humane. The divine required submission to the authority of gods; the heroic, submission to the aristocracy; and the humane, submission to human-made laws. Interestingly, the current emphasis on return to *shariah* laws, advocated by Muslim fundamentalists, is a return to the most “primitive” form of society according to Vico’s analysis. The assumption of stages of development of cultures continued until the 20th century (e.g., Wundt, 1900–1914, trans. 1916). The concept of culture as shared norms and customs or shared mentalities was used to explain the diversity among the people encountered. This concept is found also in the 20th century, with Geertz (1973) defining *culture* as shared meanings.

By the 18th century, Vico (1744/1970) used the concept of culture (he called it “nation”) to include language, myth, art, custom, religion, and so on. Culture interacted with “mind” to produce what researchers in the 20th century called “context-specific competencies” (Laboratory of Comparative Human Cognition, 1983) and “multiple realities” (Shweder, 1990).

Cultural relativism began very tentatively at the end of the 18th century when Herder

(1784/1969) argued that psychological processes depend on time and place. Linguistic analyses were incorporated in a *Völkerpsychologie* that started with von Humboldt (1820/1969), who argued that there was a close relationship between language and thought, a position that later became known as the Sapir–Whorf hypothesis. But by advocating the study of collective mental phenomena, Lazarus and Steinthal (1860) were the “real” founders of *Völkerpsychologie*. The new discipline was to occupy a position intermediate between the humanities and the natural sciences. They argued that a psychology without a historical framework is bound to remain incomplete. In 1860, Lazarus occupied the First Chair of Psychology in Bern, Switzerland, as “Professor of *Völkerpsychologie*” (Jahoda, 1993). Steinthal (1858) advocated the study of language as central to psychology and the key to understanding of the “souls” of the people who are its speakers. In addition, folklore and religion would provide the data needed to understand psychology in a broader framework.

Wilhelm Wundt’s 10-volume opus on the subject (Wundt, 1900–1914) was the most impressive presentation of *Völkerpsychologie*. He considered the study of language, myth, religion, and the like to have similar significance for understanding collective consciousness, just as cognition, feeling, and will are significant for understanding individual consciousness. Wundt derived culture from psychology, which may have been a mistake, though it is half of contemporary cultural psychology that sees “culture and psyche making each other up” (Shweder, 1990, p. 24). Berry (1983) thought that perhaps interest in Wundt would increase because of developments in contemporary psychology. For example, the substantial recent interest is the study of religion (Tarakeshwar, Stanton, & Pargament, 2003; Triandis, 2006) was an important component in Wundt’s work.

The 19th century produced many race-related theories of differences in customs and the like (Jahoda, 1993, Chapter 6). Some claimed that there was a resemblance between a Negro brain and that of an ape. Others claimed that civilization was entirely the product of an “Arian” race. Because race explained cultural differences, these authors had nothing to say about culture.

A contrasting view proclaimed the “psychic unity of mankind” (Waitz, 1859, trans. 1863). Waitz’s *magnum opus*, in six volumes, was his

Anthropologie der Naturvölker (1859). Similar to Pritchard (1843/1848), who stated that the “same inward and mental nature is to be recognized in all the races of man” (p. 546), he emphasizes the similarities in human institutions and mental characteristics. Waitz argued that there is tremendous variability within groups, an argument that can be found more recently in Minturn and Lambert’s (1964) empirical demonstration of more within- than between-cultures variance. Empirical support for the psychic unity of mankind thesis was provided by Bastian (1860), who visited several cultures in the South Pacific and the Americas. He argued that some elementary ideas can be found in all cultures. Recent empirical support of this view was obtained by Osgood, May and Miron (1975), who found that in all the cultures tested, meaning was reflected in evaluation, potency, and activity judgments.

Empirical developments were started in 1799 by the Observateurs de l’Homme (Jahoda, 1993), who formulated detailed manuals for how to collect data in other cultures. However, practical difficulties made competent data collection rare.

By the end of the 19th century, Tylor provided a broad definition of culture: “. . . the complex whole which includes knowledge, belief, art, morals, law, custom, and many other capabilities and habits acquired by man as a member of society” (1871, p. 1). Tylor (1889) for the first time also correlated two attributes of culture (avoidance patterns among relatives, e.g., husband and mother-in-law; and residence patterns, such as living in the same household) across 350 societies. He showed that there was a positive correlation. This was the first holocultural study (see Naroll, Michik, & Naroll, 1980), a type of research that is carried out today by many members of the Society for Cross-Cultural Research. When Tylor presented this method, Francis Galton (Darwin’s cousin), who was in the audience, pointed out that the computation of the significance of a correlation requires that the data be independent, and cultural diffusion can make them nonindependent. This is now called “Galton’s problem,” and can be solved in several ways (Naroll et al., 1980), such as making sure that the cultures sampled are geographically distant from each other.

Also at the end of the 19th century, expeditions were undertaken to obtain “mental measurements” (Rivers, 1901, 1905). Rivers ob-

tained evidence that some natives studied during his expedition were *less* susceptible to some and *more* susceptible to other visual illusions than were Europeans. This finding anticipated the work of Segall, Campbell, and Herskovits (1966). In the late 19th century the framework provided by Darwin's theory of evolution started influencing psychology and has remained influential (Campbell, 1975).

THE 20TH CENTURY

Boas (1911/1938) emphasized that ethnocentrism must be replaced with an appreciation of each culture. His students were most influential and included Sapir (1921), who formulated the Sapir-Whorf hypothesis, which I discuss later; Benedict (1934/1959), who viewed cultures as integrated wholes; Mead (1928), who became famous for her studies of Samoa and New Guinea (1930), and argued that much that passes as biologically determined is in fact culturally determined (Mead, 1935); and Herskovits (1948, 1955), who was a most articulate exponent of cultural relativism. Thurnwald (1912, mentioned by Jahoda, 1993) advocated the intensive study of particular cultures, a position that later in the century was advocated by indigenous and cultural psychologists.

Bartlett (1932/1950) produced a classic work when he studied memory among the Swazi and argued that cross-cultural investigations yield important results of both theoretical and practical significance.

The mid-20th century included intensive discussions of culture and personality. However, these discussions were assessed by Bruner (1974) as "magnificent failures." This observation reflects in part the lower status of psychoanalysis in contemporary psychology, and the observation that data at the cultural and individual levels of analysis are often independent of each other (Hofstede, 1980). More recent discussion of the topic took very different directions, focusing on dimensions of cultural variation and cultural syndromes (Triandis, 1997; Triandis & Suh, 2002). It is too early to tell whether these directions will be influential.

An important influence on social psychology, in the middle of the 20th century was Kluckhohn's (1954) chapter, "Culture and Behavior," in the *Handbook of Social Psychology* and Klineberg's (1954) text, which used

much cultural material. Both publications were studied with much care and quoted extensively by the cross-cultural psychologists who emerged in the 1960s and 1970s. Klineberg (1980) provided an account of why he included so much anthropological material in his social psychology text. He had become "converted" in interaction with Boas, Sapir, Benedict, and Mead.

Anthropologists have been debating for more than a century the best way to define "culture." They are still discussing this problem (Borowsky, Barth, Shweder, Rodseth, & Stolzenberg, 2001). Some define it as shared "practices" (what people do) and others, as shared "meanings." Shweder, in Borowsky et al., favored the definition by Redfield (1941): "Culture is shared understandings made manifest in act and artifact" (p. 1). Herskovits (1948, 1955), defined "culture" as the human-made part of the environment. Based on that definition, Triandis (1972) distinguished objective and subjective culture. "Objective culture" includes concrete and observable elements such as artifacts (e.g., tools, bridges), institutions and social structures. "Subjective culture" includes categorizations (language), evaluations, beliefs, attitudes, stereotypes, expectations, norms, ideals, roles, task definitions, and values. Psychological methods were proposed to study these constructs, and examples were provided with the study of stereotypes, roles, and values. The data for these studies came from Greece, India, Japan, and the United States. A recent publication influenced by this approach is that of Adamopoulos and Kashima (1999).

The 20th century has been characterized by multiple definitions of culture. Among the most interesting are the following: "Culture is to society what memory is to individuals" (Kluckhohn, 1954). It includes what "worked" in the experience of a society, so that it was worth transmitting to future generations. Sperber (1996) used the analogy of an epidemic: A useful idea (e.g., how to make a tool) is adopted by more and more people and becomes an element of culture. Barkow, Cosmides, and Tooby (1992) distinguished three kinds of culture: metaculture, evoked culture, and epidemiological culture. They argued that "psychology underlies culture and society, and biological evolution underlies psychology" (p. 635). The biology that has been common to all humans, as a species distinguishable from other species, results in a "metaculture" that

corresponds to panhuman mental contents and organization. Baumeister (2005), in *The Cultural Animal*, explicitly states that he is talking about the metaculture, and is therefore not interested in cultural differences. Biology in different ecologies results in “evoked culture” (e.g., a hot climate leads to light clothing), which reflects domain-specific mechanisms triggered by local circumstances and leads to within-group similarities and between-groups differences. Sperber’s (1996) conception of culture was called “epidemiological culture” by Barkow et al. (1992).

Klineberg’s (1980) history of social psychology covers several topics that were important before 1960. Is thought influenced by language? The so-called Whorfian hypothesis was the focus of much interest before 1960, and a weak version of the theory has received some empirical support even recently (see review in Triandis, 1994). For example, people who have a language that does not have terms for “green” and “blue” show less differentiation among color chips that include these colors than English speakers when making multidimensional scaling judgments.

Klineberg (1980) also discussed perception and memory; the application of projective techniques; psychoanalysis; Piaget’s contributions, modified by the cross-cultural work of Dasen (1972); the application of tests, the problem of national character; the study of national stereotypes, psychopathology, authoritarianism, leadership, field-dependence, acculturation, and the achievement motive.

A theme detectable across all this work is the mutual influence of anthropology and psychology. Psychological statements that are supposedly universal were challenged by anthropologists. For example, Freud’s suggestion of the universality of the Oedipus complex was challenged by Malinowski (1927a, 1927b), who argued that there is among the Trobrianders a “matrilineal complex” in which boys show a repressed hatred for their mother’s brother, who is the main source of discipline, authority, and executive power in that society. Statements made by anthropologists were criticized by psychologists (e.g., that they disregard individual differences within culture when they study only a few “informants” to learn about a culture).

An important achievement of early studies of the relationship between culture and psychology was the demonstration that even a basic

process such as perception is influenced by culture (Segall et al., 1966). This was followed by work on the relationship between culture and cognition, such as that of Witkin and Berry (1975). During the early part of the 21st century, important work on culture and cognition was done by Nisbett (2003) and his students. Berry’s work on culture and cognitive differentiation did not have much impact, because Berry became disappointed when his predictions were not supported by some data he collected in Africa, and he turned to other research topics. Cronbach and Drenth (1972) outlined how mental tests may be adapted to other cultures.

Much of the work up to 1978 or so was summarized in the first edition of the *Handbook of Cross-Cultural Psychology* (Triandis, General Editor, 1980–1981), which included volumes with coeditors on perspectives (William W. Lambert), methodology (John Berry), basic processes (Walter Lonner), developmental psychology (Alastair Heron and Elke Kroege), social psychology (Richard Brislin), and psychopathology (Juris Draguns). A second edition of this handbook was published in 1997 in three volumes by Berry and his coeditors. Munroe, Munroe, and Whiting (1981) published the *Handbook of Cross-Cultural Human Development*.

Some discussions of culture have focused on specific elements or processes. For example, Triandis (1994) stressed shared standard operating procedures, unstated assumptions, norms, values, habits about sampling the environment, and the like. Because perception and cognition depend on the information sampled from the environment and are fundamental psychological processes, this culturally influenced sampling of information is of particular interest to psychologists. Cultures develop conventions for sampling information from the environment (Triandis, 1989), and also implicit agreements about how much to weigh the sampled elements. For example, people in hierarchical cultures are more likely to sample clues about hierarchy than clues about aesthetics.

CONTEMPORARY VIEWS

There are many definitions of *culture* (Kroeber & Kluckhohn, 1952), but almost all researchers see certain aspects as characteristics of culture. First, culture emerges in adaptive interac-

tions between humans and environments. Second, culture consists of shared elements. Third, culture is transmitted across time periods and generations. Consider each of these aspects of culture in turn.

Humans Interact with Environments

As people interact with others in their physical and social environments, they reach agreements about how to behave together. The psyche develops through interaction with the social environment (Nisbett, 2003). Social relationships are internalized and become part of human psychology (Vygotsky, 1978, 1987). Parts of culture, such as words and tools, become internalized, and as a result the mind is shaped by culture. Thus, humans are expressions of their culture.

This view of culture as adaptive to environmental context has a long history (Jahoda, 1995). Even now (e.g., Berry, 2003), it considers that culture is both constrained and shaped by a group's habitat, leading to the use of the term *ecocultural* to describe it. People develop language, writing, tools, skills, and definitions of concepts. They determine ways of organizing information, symbols, evaluations, and patterns of behavior; intellectual, moral, and aesthetic standards; knowledge, religion, and social patterns (e.g., marriage, kinship, inheritance, social control, sports); systems of government, systems of making war; and expectations and ideas about correct behavior that are more or less effective (functional) in adapting to their ecosystem.

One way to think of cultural evolution (Boyd & Richerson, 1985) is to think of Darwinian mechanisms (Campbell, 1965); that is, people try this and that and some of what they try works, so they select it for transmission to their children and friends. Elements of culture that were effective (e.g., that resulted in satisfying solutions to everyday problems of existence), became shared and were transmitted to others (e.g., the next generation of humans).

These elements often reflect unstated assumptions and result in standard operating procedures for solving the problems of everyday life. Thus, they become aspects of culture. However, circumstances keep changing, and what was functional in one historical period (e.g., having six children when infant mortality was very high) can become dysfunctional in another. But members of cultures do not shed easily the dysfunctional elements. Thus, many ele-

ments of culture are dysfunctional (Edgerton, 1992). For instance, Friedl (1964) described a phenomenon called "lagging emulation": As lower status people acquire enough wealth, they emulate the obsolete customs of higher status people! We might argue that this is not functional, but we must remember that people may derive satisfaction even from behaviors that are no longer functional. Many of our behaviors, clothes, features of our houses, and so forth, are no longer functional.

Shared Elements

Two kinds of shared elements are important: shared practices and shared meanings.

One issue of importance in the study of culture and psychology is how to specify the limits of culture. One way of doing this is to look for shared elements. For example, do people share a language? It is also useful to consider shared time and place. People who share a language, a time period, and a geographic region are most likely to be able to interact, and to develop shared meanings (i.e., to belong to the same culture). Granted, interactions can also take place among individuals who do not share a language (e.g., via interpreters), time (e.g., reading a book written centuries earlier), or place (e.g., via satellite). But most interactions occur when people share a language, time, and place. Diffusion and acculturation are also important ways that cultures influence each other (see below). Furthermore, what has worked in one historical period is often used in other historical periods.

Common fate and other factors resulting in easy interaction among individuals can also result in the formation of cultures or subcultures. Thus, nations, occupational groups, social classes, genders, "races," religions, tribes, corporations, clubs, and social movements may become the bases of specific subcultures.

How many cultures are there? "Hundreds of thousands" is probably a correct answer. The question of the definition of the boundary of a culture has been discussed in anthropology, in which one proposal is to use a double boundary; that is, culture is delimited when people on both sides of a boundary do not understand the language spoken on the other side of the boundary (Naroll, 1971). Thus, because laypeople do not understand the language of medicine does not make medicine a separate culture, because physicians do understand the language of laypeople.

Although there are thousands of cultures, fortunately for the purpose of studying them there are similarities among different cultures. For example, Europe and North America, when viewed from a global perspective, are relatively similar; Africa South of the Sahara, South Asia, East Asia, Polynesia, and different regions of the Americas, where Native Americans can be found, have more elements of culture in common than elements that are different. Thus, anthropologists talk about “cultural regions” such as Africa South of the Sahara (Burton, Moore, Whiting, & Romney, 1996). Of course, there are thousands of cultures in Africa, yet they have some elements in common, so we can consider Africa South of the Sahara a cultural region. There is disagreement among anthropologists concerning how many cultural regions there are, but the consensus of opinion seems to be between six (Murdock et al., 1950) and 10 (Burton et al., 1996).

Even within a culture there is a tremendous variation in personalities, yet there are some things that most English people, for example, have in common, so we can call England (with a distinct language, history, food, dress, etc.) a culture that is different from, say, France or Germany.

Thus, we can conceive of a tree with its trunk comprising the metaculture (universal elements; Barkow et al., 1992), six to 10 major branches, and each branch having scores of minor branches, with the leaves represented by thousands of subcultures.

Attributes such as nationality, religion, “race,” or occupation are not appropriate criteria for defining cultures. The use of a single criterion is likely to lead to confusion, as would happen if all people who eat pizza were placed in one category. Culture is a complex whole, and it is best to use many criteria to discriminate between one culture and another. Most modern states comprise many cultures; most corporations have unique subcultures; and most occupations have distinct subcultures.

Cultures are in constant flux, but the change tends to be slow. Some elements of culture do not change much. For instance, whether people drive to the right or left usually does not change. Other elements change slowly, requiring one or two generations before there is a major transformation. Still other elements change quickly. The meaning of some terms changes in years or decades rather than in centuries. For example, what was called “cool” in 1950 and in 2000 is rather different.

Transmission to Others

Cultural elements are transmitted to a variety of others, such as the next generation, coworkers, colleagues, family members, and a wide range of publics through a process of *enculturation*. A distinction has been made between three forms of cultural transmission: *vertical*, *horizontal*, and *oblique* (Berry, Poortinga, Segall, & Dasen, 2002). Vertical transmission takes place from parents to offspring, thus paralleling that of genetic forms of transmission. These two forms of transmission are usually entwined, so that their relative contributions to behavior in the second generation cannot be allocated easily. In horizontal transmission, human behavior is influenced by peers (within generations) and is more of a mutual process than is parent-child (vertical) cultural transmission. Finally, oblique transmission takes place when social institutions (e.g., schools, media) that already preexist an individual in a society influence the developing individual. These latter two forms are entirely cultural and have no genetic aspects (Berry & Triandis, 2004).

Another form of transmission takes place from outside a person’s own cultural group as a result of direct contact (e.g., colonization, migration) or indirect influence (e.g., telemedia or books). This form of cultural transmission, termed “acculturation” (Chun, Balls-Organista, & Marin, 2002), is responsible for changing existing behaviors and introducing new ones. Thus, rather than providing a basis for cultural continuity (as enculturation does), acculturation serves as a cultural source of discontinuity, and even disruption in some cases (Berry & Triandis, 2004).

These considerations led to the most satisfying definition of *culture*: “Culture consists of explicit and implicit patterns of historically derived and selected ideas and their embodiment in institutions, practices, and artifacts; cultural patterns may, on one hand, be considered as products of action, and on the other as conditioning elements of further action” (Adams & Markus, 2004, p. 341).

Concepts and Methods

The post-1970 period resulted in the development of concepts and methods especially appropriate for cross-cultural and cultural psychology. Emic and etic concepts are an example. *Emics* are concepts that are unique to

one culture. *Etics* are concepts that can be found in most, if not all, cultures. Pike (1967), developed these terms, inspired by the difference between *phonetics* and *phonemics* (for details, see Triandis, 1964; Berry, 1999). Some students of culture assume that every culture is unique. In some sense, every object in the world is unique. However, science is an attempt to understand the world as simply or as parsimoniously as possible. The glory of science is that very diverse phenomena can be understood by identifying the underlying similarity. For example, Newton “showed that the same force that pulls an apple to Earth keeps the Moon in its orbit and accounts for the revolutions of the then recently discovered moons of Jupiter in their orbits about that distant planet” (Sagan, 1980, p. 69).

Thus, the core issue is whether a scientist is interested in the specific (emic) elements of culture and/or the elements that are broadly shared (etic elements). In psychology this is not a simple dichotomy. There are elements of culture found only in one culture, in a cultural region, and across cultures. For example, there are cultural elements found only in one particular hunter-gathering culture, such as a tribe in the Kalahari Desert (e.g., DeVore & Konner, 1974); elements that are shared among hunters and gatherers, such as low hierarchical differentiation when there is no way to accumulate and preserve food; and elements that are common across cultures, such as collectivism or individualism (Triandis, 1995). Carpenter (2000) discovered the tendency for tight cultures to be more collectivist by correlating materials from the Human Relations Area Files across cultures.

Many of the elements of culture, such as ideas, patterns of behavior, and standards of evaluation, are specific to each culture, but they are often of limited interest. Many cross-cultural psychologists find of greater interest the common or etic elements observed in cultural patterns. But, as argued by Pike (1967), emics can be systematically related to etics. For instance, the concept of “social distance” is an etic. In all cultures people feel close to some other people and far from others (e.g., members of the same family feel close to each other and far from people on another continent). But the way that concept is expressed differs from culture to culture. In the northern United States, in 1900, the distance between whites and blacks was large, and a reliable clue of social distance was barring blacks from the neighborhood. In the 21st century, that clue is

no longer valid as a measure of social distance. Nowadays, a better clue might be rejection from a club or job discrimination. In India, the same idea is expressed by rejecting people from one’s kitchen, because the concept of ritual pollution specifies that one should not allow people of a lower caste to touch one’s earthenware. Thus, different emics can be used to reflect the same etic.

Methodologically, we can ask people in different cultures to tell us where a particular emic behavior is located on a social distance scale that ranges from “to marry” to “to kill.” Then we can empirically obtain the scale value of the emic behavior in each culture (Triandis, 1992). That is the first step. In the second step, we study a new sample and use the previously obtained scale values for each behavior item. For example, we might present a particular social stimulus, such as “An African American physician” to people from different cultures, and ask them to indicate whether they are likely to use each of the previously scaled behaviors toward that stimulus person. The participants in each culture respond to emic behaviors of their own culture when making these judgments. But because we know the scale value of each emic behavior on the etic scale, we can compute the social distance in etic units of measurement, so we can compare the cultures. We can, for example, say that an African American physician is more acceptable in one culture than in another (Triandis, 1967, 1992).

In short, when we study cultures for their own sake we may well focus on emic elements, but when we compare cultures we have to work with the etic cultural elements.

Berry et al. (2002) outlined three theoretical orientations to the relationships between culture and psychology: *absolutism*, *relativism*, and *universalism*. The *absolutist* position assumes that human phenomena are basically the same (qualitatively) in all cultures (e.g., any personality trait found in one culture is exactly the same as that personality trait in all other cultures; any mental illness is exactly the same in all cultures). From the absolutist perspective, culture is thought to play little or no role in either the meaning or the display of human characteristics. Assessments of such characteristics are made using standard instruments (perhaps with linguistic translation), and interpretations are made easily, without taking into account alternative, culturally based views.

In sharp contrast, the *relativist* approach assumes that all human behavior is culturally

patterned. It seeks to avoid ethnocentrism by trying to understand people “the way the natives see the world.” Explanations of human diversity are sought from within the cultural context in which people have developed. Assessments typically employ the values and meanings that a cultural group gives to a phenomenon. Comparisons are judged to be problematic and ethnocentric, and are therefore virtually never made.

A third perspective lies between absolutism and relativism. *Universalism* assumes that basic psychological processes are common to all members of the species (i.e., constituting a set of psychological givens), and that culture influences the development and display of these processes (i.e., culture plays different variations on these underlying themes). Assessments are based on the underlying process (etics), but measures are developed in culturally meaningful versions (emics). Comparisons are made cautiously and employ a wide variety of methodological principles and safeguards (Triandis & Berry, 1980), whereas interpretations of similarities and differences take alternative, culturally based meanings into account (Berry & Triandis, 2004).

Up to the 18th century, the absolutist perspective was dominant. In the last part of the 18th century, some support for the relativist perspective emerged and became strong in the 19th century, and especially in the early 20th century. The third perspective emerged in the middle of the 20th century. Currently all three perspectives can be found, though the relativist and universalist perspectives are now dominant.

While few today advocate a strictly absolutist view, the relativist/emic position has given rise both to “indigenous psychology” (Kim & Berry, 1993; Yang, 1981), and “cultural psychology” (Shweder, 1990). An important element in one kind of cultural psychology is intensive ethnographic work; it emerged from anthropology. Another kind of cultural psychology uses experimental methods, with random assignment of participants, in more than one culture (e.g., Hong, Morris, Chiu, & Benet-Martinez, 2000). This development emerged from social and experimental psychology.

Indigenous psychology examines the meaning systems of a particular culture, with emic concepts and methods. For example, Yang (1981) examined the interplay between traditional Chinese culture and modernity in Tai-

wan. Most indigenous psychologists study their own culture but have been trained in the West. The goal of indigenous psychology is to convert the “folk psychological theory” of that culture into a scientific psychological theory. The methods tend to be standard psychological methods, and university students are the most common participants. Berry et al. (2002) and Berry and Kim (1993) claimed that indigenous psychologies, although valuable in their own right, serve an equally important function as useful steps on the way to achieve a universal psychology.

Some cultural psychology focuses on one culture and uses mostly ethnographic methods, such as observations, interviews, focus groups, and analyses of texts in intensive accounts of that culture. The researcher, usually from a Western culture, studies a village culture. Thus, the participants are often nonliterate members of a culture, which makes the use of most psychological methods inappropriate. This perspective is favored particularly by developmental psychologists (e.g., Greenfield, 2000; Rogoff, 1990) while examining how the culture of the parents becomes incorporated in the culture of the children. In other kinds of cultural psychology (e.g., Hong et al., 2000) participants are assigned randomly to two conditions. For example, after participants receive a prime from a collectivist or individualist culture, their responses on some individualism–collectivism scale are assessed. A typical finding is that participants from collectivist cultures give collectivist responses, but this tendency is augmented when they receive the collectivist prime; similarly, participants from individualist cultures give individualist responses, but they are more extreme when they receive an individualist prime. The important point is that participants can temporarily “change culture” when they receive the appropriate prime. This tells us that both the stimuli received from the environment and culturally shaped internally wired-in factors determine the responses.

A related issue is whether culture should be conceptualized inside or outside the person. Triandis (1980) introduced the *Handbook of Cross-Cultural Psychology* with the definition: “Cross-cultural psychology is concerned with the systematic study of behavior and experience as it occurs in different cultures, is influenced by culture, or results in changes in existing cultures” (p. 1). The first part of this definition makes explicit that culture is outside

the person. In that case, culture is represented by an *index* rather than by a *process* (Greenfield, 2000). The last part of the definition suggests that people may change the culture, so that “culture and psyche make each other up” (Shweder, 1990, p. 24). Culture is now viewed as meanings embodied in cultural artifacts. Thus, it emerges when the inside meets the outside.

Up to about 1950, the dominant view in both anthropology and psychology was that culture is outside the person. At that time, culture was considered as a kind of experimental treatment (Strodtbeck, 1964). In the 1980s, many researchers started emphasizing that culture is also inside the person (Shweder & LeVine, 1984). In other words, the recent view is that the internalization of aspects of culture has influenced all psychological processes (Vygotsky, 1987); this view is held especially by “cultural psychologists” (e.g., Cole, 1996) and indigenous psychologists. Currently, those identified as “cross-cultural psychologists” accept both perspectives (e.g., Berry, 2000; Triandis, 1972, 1980, 2000).

In my opinion, the differences between cross-cultural and cultural psychology are small. There is considerable variability among the studies that can be classified as one or the other psychology. For example, both questionnaire studies and studies that use the Human Relations Area Files qualify as cross-cultural psychology. Ethnographic and experimental studies can be found in cultural psychology. But Triandis (1972) included not only a chapter on values, with data from Japan, India, Greece, and the United States, that fits the definition of cross-cultural psychology, but also a chapter that focuses on meanings in Greece (Triandis & Vassiliou, 1972), which most psychologists would consider cultural psychology.

In fact, the differences are of emphasis rather than of qualitative substance. Specifically, cross-cultural psychologists emphasize content more than context, and cultural psychologists emphasize context more than content. Cross-cultural psychologists emphasize that culture is outside the person, and cultural psychologists, that it is inside the person. But in fact it is both inside and outside.

Cross-cultural psychologists tend to study attributes of culture that do not change much over time. For instance, Bond and Smith (1996) found that conformity is high in collectivist cultures; Carpenter (2000) found that collectivist

cultures are tight; Diener, Diener, and Diener (1995) found higher levels of well-being in individualist cultures.

Cultural psychologists tend to study less stable attributes, such as meanings or conceptions, for example, how the “self” is conceived in different cultures.

Cross-cultural psychologists are more likely to use questionnaires and collect data in many cultures, whereas cultural psychologists are more likely to use intense ethnographic work or experiments and collect data in a few cultures. As a result, cross-cultural psychologists consider differences in meaning barriers to overcome with elaborate psychometric methods, whereas cultural psychologists focus their research on differences of meaning (Cole, 1996; Shweder, 1990).

Cole characterized cultural psychology by its emphasis on mediated action; its inclusion of historical, ontogenetic, and microgenetic levels of analysis; and its grounding in everyday life events. Mind emerges in the interactions of people. Individuals are active agents of their own development. Cultural psychology, according to Cole (1995) draws methodologies from the humanities, as well as from the social and biological sciences, and rejects cause-effect explanations in favor of analyses that emphasize the emergent nature of mind in activity, which requires interpretations of events that have different meanings.

There is also a difference that reflects the topics under study. Cross-cultural psychologists are often industrial/organizational or political psychologists, whereas cultural psychologists are more often developmental or social psychologists. Developmental psychologists are especially likely to study very different (e.g., exotic) cultures, with ethnographic methods (e.g., Greenfield’s work in 1990 on how children learn to weave in Zinacanteco culture), whereas organizational psychologists study highly developed cultures with psychometric instruments. For example, Huang and Van de Vliert (2004), who examined the job satisfaction of 129,087 respondents in 39 countries, found that those who had higher job status were more satisfied, but this occurred only in the individualist countries and when jobs provided individuals the opportunity to use their skills and abilities.

Each of these approaches has advantages and disadvantages (Triandis, 2000), so it seems desirable to combine the approaches, to use

multimethod approaches, and to look for the convergence of findings across approaches.

Recent reviews of the literature, such as that of Lehman, Chiu, and Schaller (2004), have sections on empirical studies supporting both the cross-cultural and cultural psychology perspectives. In short, culture is both outside the person (a set of practices shared by the group, and existing prior to any particular individual) and inside the person (influencing a person's behavior by providing interpretive perspectives for making sense of reality as a result of enculturation). Indigenous and cultural psychologists favor the view that culture is inside the person, in the sense that most psychological processes are shaped by culture. They try to develop a psychology that is satisfactory for understanding a particular culture. Indigenous psychologists do this by identifying categories and linguistic elements that are more or less unique in a particular culture. For example, the Japanese concept called *amae* means something like "indulgent dependency" (Doi, 1973), one interpretation of which is "to tolerate the other person's dependence." This concept does not exist as a single word (monolexemic) in other languages. Monolexemics tell us that the idea is used frequently in a culture (Zipf, 1949), and that it is really important in that culture. The fact that there is no monolexemic term in European languages that means the equivalent of *amae* means that the concept is a Japanese emic. The judgment that *amae* is important in Japan is in agreement with expert analyses of Japanese psychology (Doi, 1986). In short, indigenous psychologists have a way of getting at the *most important ways of thinking* in a particular culture.

Cultural psychologists study most intensively a few cultures and look for the way psychological processes are influenced by culture. For example, Kitayama, Markus, Matsumoto, and Norasakkunkit (1997) generated 400 Japanese and 400 American situations, and found that the Japanese situations tend to decrease self-esteem, whereas the American situations tend to increase it. A variant of cultural psychology, ethnopsychology, looks at different theories of the mind in various ethnic groups (Lillard, 1998).

Still another issue is whether culture should be conceived as consisting of an arbitrary code or an organized configuration of elements. Culture has been discussed as both an arbitrary code (D'Andrade & Romney, 1964), and as a config-

uration of cultural elements organized around a theme. For instance, Triandis (1996) proposed that "cultural syndromes" can be identified, such as individualism, collectivism, verticality, horizontality, tightness (or uncertainty avoidance), and masculinity (Hofstede, 1980, 2001), in which cultural elements are interrelated so as to form coherent wholes centered around the importance of the individual, the collective, rank, equality, close observance of norms, and gender differentiation, respectively.

Triandis (1995) argued that corresponding to each cultural syndrome are personality patterns. *Idiocentrics* behave and feel like most people in individualist cultures; *allocentrics* behave and feel like most people in collectivist cultures. However, although collectivism and individualism are opposite cultural patterns, idiocentrism and allocentrism are orthogonal to each other. People in all cultures have both idiocentric and allocentric cognitions, but they use them more or less depending on the situation. Thus, when idiocentrics and allocentrics were randomly assigned to situations that were collectivist or individualist (an experimental treatment that simulated the two types of culture), the allocentrics in collectivist situations were most cooperative, whereas the idiocentrics were not cooperative, and even the allocentrics in individualist situations were not especially cooperative (Chatman & Barsade, 1995). Thus, neither personality nor situation predict behavior. Rather the interaction between two cognitions—one derived from personality shaped by culture and the other reflecting the situation—results in behavior. Furthermore, an as yet unpublished psychiatric study found that allocentric Americans and idiocentric Turks have poor mental health. Americans who are moderately idiocentric and Turks who are allocentric have good mental health. Thus, if there is a good fit between personality and culture, individuals are mentally healthy. Finally, allocentrics who spend several years in an individualist culture have very high levels of both allocentrism and idiocentrism (Yamada & Singelis, 1999).

It is also important to think of some aspects of culture as enduring even though the people who created them are no longer alive (Kroeber, 1917). Individuals come and go, but cultures remain more or less stable. For example, a behavior pattern such as driving on the left side does not change even though the people who started it are no longer alive.

Functions of Culture

Recent reviews of the literature, such as that by Lehman et al. (2004), emphasize that culture has functions such as allowing people to understand their position in the cosmos. This reminds us of Katz (1960), who identified four functions of attitudes. Cultures have parallel functions, and Katz identified four functions:

1. The *adjustment* function allows people, in the course of interaction with the environment, to maximize the rewards and minimize the penalties. Many culture theorists (e.g., Whiting, 1973/1977, 1994) have emphasized that cultures help individuals adjust to their ecology. Certainly, cultures provide norms, which furnish guidance for behavior and maximize the chances that people will receive appropriate rewards.
2. The *ego-defensive* function allows the individual to protect the self from uncomplimentary truths. Because members of all cultures are ethnocentric (discussed earlier), they compare themselves to other cultures in ways that increase their self-esteem. High self-esteem is functional because it protects individuals from becoming devastated when they are criticized.
3. The *value expressive* function allows people to derive pleasure by expressing their basic values. Values are a central element of culture (Schwartz, 1992) that function to provide guidance in life.
4. The *knowledge* function allows people to understand their position in the universe and to predict events. Religion is an aspect of culture (Tarakeshwar et al., 2003) and one of its main functions is to provide an understanding of the relationship between humans and the cosmos (Swanson, 1960). The epistemic function of culture is emphasized by Lehman et al. (2004), who reviewed empirical research supporting it.

Biology constrains the development of culture. Certain aspects of culture develop more readily, and other aspects develop with great difficulty because biology interacts with the development of culture.

Recent Examples of the Impact of the Concept of Culture on Psychology

The study of the relationship of culture and psychology in the second half of the 20th century went through four phases: (1) the culture

and personality work, (2) the emphasis on universalism, (3) the emphasis on cultural syndromes, and (4) the integration of the cultural perspectives with work in mainstream psychology and the other social sciences. I comment about each of these below.

Culture and Personality

This phase occurred primarily between 1950 and 1970. Bruner (1974) called it a “magnificent failure,” because one cannot measure personality out of context, then use the information to characterize a culture. He argued also that after 30 years of work on this topic, no reliable findings were widely accepted.

Universalism

This phase was observed especially in the period between 1970 and 1980. In the previous phase there was much emphasis on relativism. In this phase the stress was placed on universalism. Work by Ekman (1972) and Osgood et al. (1975) emphasized universal categories of emotion or meaning. However, Shweder and Bourne (1982) were skeptical about this kind of universalism, because it used a very high level of abstraction, so that both “God” and “ice cream” are good, potent, and active.

Cultural Syndromes

This phase had its peak in the period between 1980 and 2000. The focus was on cultural syndromes (Triandis, 1996) such as cultural complexity (Draper, 1973), tightness, and especially collectivism and individualism (Triandis, 1994, 1995). Such dimensions result in a psychological phenomenon being different in cultures with high or low incidence on a syndrome. For example, the way the “self” is defined is different when the culture is collectivist rather than individualist (Triandis, 1989). People in individualist cultures (Western Europe, United States, Canada, Australia, New Zealand) sample with high probability elements of the personal self (e.g., “I am busy,” “I am kind”) and internal processes (e.g., attitudes, beliefs, personality) as predictors of behavior. People from collectivist cultures (many traditional cultures, the cultures of East Asia), tend to sample mostly elements of the collective self (e.g., “My family thinks I am too busy,” “My coworkers think I am kind”) and aspects of the external environment (e.g., group memberships, norms, social pressures,

roles) as predictors of behavior (Triandis, 1995; Triandis, McCusker, & Hui, 1990; Trafimow, Triandis, & Goto, 1991). The self has much social content in collectivist cultures (e.g., “I am an uncle,” “I am a member of the communist party”) and little such content in individualist cultures (e.g., “I am hardworking,” “I am happy”; Triandis et al., 1990). Much research (e.g., Triandis & Suh, 2002) focuses on individualism and collectivism and the presence of an independent or relational or interdependent self (Kagitçibasi, 1996; Markus & Kitayama, 1991) having a particular form in certain kinds of culture. Other conceptions have examined culture-sensitive taxonomies of activities (Cole, 1995) or action in action-in-context (Eckensberger, 1995).

Integration of Culture and Mainstream Psychology

This phase started about 1985 and continues to the present. The main emphasis is that the fundamental principles of psychology may depend on culture. Much of the work employs experimental methods, and shows that culture modifies an important psychological process that was hitherto considered to be universal. Representative publications include those by Choi, Nisbett, and Norenzayan (1999), Cole (1995, 1996), Hong et al. (2000), Iyengar, Lepper, and Ross (1999), Kitayama and Markus (1994), Kitayama et al. (1997), Markus and Kitayama (1991), Miller (1984), Nisbett (2003), and Shweder (1990).

Overview of the Various Phases

As we look at the four-phase development of the field, a major theme has been that psychological processes are probably shared features of our species, but behavioral expression must be understood in the context of the culture in which a person develops. There are some psychological universals (Lonner, 1980), but they deal with phenomena that are at a high level of abstraction and serve as a basis for making cross-cultural comparisons. Other phenomena, at intermediate and low levels of abstraction, are more enveloped by culture, making comparisons more difficult. Thus, there are both universalistic and context-specific views of the development of cognition (Laboratory of Comparative Human Cognition, 1983), perception (Segall et al., 1966), learning (Brislin & Horvath, 1997; Tweed & Lehman, 2002), affective meaning (Osgood et al., 1975), emotion

(Kitayama & Markus, 1994; Mesquita, 2001), facial expression of emotion (Ekman, 1992), motivation (Markus & Kitayama, 1991), thinking (Nisbett, 2003), personality (e.g., McClelland, 1961; Triandis, 1997) and other basic processes (Berry, Dasen, & Saraswathi, 1997), communication (e.g., Gudykunst, 1991), and social behavior (Miller, 1984; Fiske, 1990; Berry, Segall, & Kagitçibasi, 1997). Many theoretical perspectives that include culture, such as evolutionary approaches, and the stress on indigenous psychologies (Berry, Poortinga, & Pandey, 1997) evolved after 1980. In fact, up to that point, most cross-cultural psychology was concerned with methods (Triandis & Berry, 1980). As the field matured, the multimethod approaches that developed found consistencies among ethnographic, survey, and experimental methods (e.g., Nisbett, 2003).

Much of pre-1980 psychology was shaped by the fact that the participants, the researchers, and editors of the major journals were members of Western individualistic cultures. A universal psychology requires expansion to include the perspectives found in all cultures.

Fortunately, after 1960, a number of psychologists born outside the West produced work that reflected their own cultures. Only the most prominent examples can be mentioned here. Chinese culture was represented by Cheung and Leung (1998), Ho (1996), Hui and Yee (1994), Hwang and Yang (2000), and Yang (2000), among others. India was reflected in the work of Pandey (1988), D. Sinha (1986), and J. B. P. Sinha (1980). Japan was studied by Kashima and Yamaguchi (e.g., Kashima et al., 1995), Kitayama (e.g., Kitayama & Markus, 1994), and Misumi (1985). Korea has been described by Kim (e.g., Kim & Berry, 1993), Choi (e.g., Choi et al., 1999), and Suh (2000). Mexico was studied by Diaz-Guerrero (1963, 1975, 1990). His son Diaz-Loving (1998) has been a strong proponent of an indigenous psychology. Turkey has been represented by Kagitçibasi (1990, 1996). The Philippines has been represented by Enriques (1990). Venezuela has been discussed by Salazar (1984).

Probable Fifth Phase

As the field matures there should be more cooperation between cultural and cross-cultural psychologists. As they jointly design projects, collect data with multimethod approaches, and write up their findings in joint papers, there

will be a natural synthesis of the various approaches. But studies already combine the two approaches. For example, Greenfield (2000) argues that individualism–collectivism is the “deep structure” of cultural differences, and “knowing that a culture is in the individualist family tells about the overall shape and meaning of the culture; this primes you for the specifics” (p. 230). She found that collectivism allowed her to place many specifics of Zinacanteco culture into a single cultural framework. She also reports an empirical study that used both psychometric and ethnographic methods. This maybe the best example of the fifth phase.

The next phase may also include greater emphasis on religion. Religion emerges under the influence of some universal psychological mechanisms (Hinde, 1999), such as the tendency to understand the world in terms of cause–effect relationships, to learn from others, and to develop self-efficacy. Most important maybe the need to control the environment, reflected in experiments in which participants prefer strong electric shocks that they control to weak electric shocks that they do not control (Averill, 1973). Furthermore, there are universal dimensions of social behavior (Triandis, 1978): association versus dissociation, and superordination versus subordination. Most primates show social behaviors that have corresponding structures, associate with members of the band, reject those who are not members of the band from their territory, and have pecking orders. Religions provide means of associating with coreligionists and dissociating (avoiding or even fighting) from those who do not belong to the ingroup. In most cultures “good gods” are in heaven and “bad gods” are below. Finally, as Freud (1964) has pointed out, though religion is an illusion, it provides wish fulfillment—“We do not die, we go to paradise”; “We are the chosen people”; “The gods are protecting us”—that is most satisfying.

It is perhaps inevitable that the study of religion will again become an important part of cultural psychology. After all, Wundt made it central to his *Völkerpsychologie*, and we might well go back to the beginning of the field and do a better job than was done previously.

ACKNOWLEDGMENT

I am grateful for critical comments on an earlier version of this chapter by John Berry, Roy D’Andrade,

Gustav Jahoda, Shinobu Kitayama, and Lee Munroe.

CHAPTER 4

Evolutionary Foundations of Cultural Psychology

MELVIN KONNER

In the 1980s and 1990s, with considerable enthusiasm, some psychologists announced that they had discovered culture. Influenced explicitly by the psychologist Lev Vygotsky, who had a brief but brilliant career in the Soviet Union in the 1920s and 1930s, they held that culture pervades every aspect of mind—that mind is in its essence “dialogic”—and that it is foolish to try to understand cognition without recognizing that it is cultural, as it were, “all the way down.” The developmental psychologists among them traced their basic theoretical stance to the year that Vygotsky’s (1962) work was published in English. Anthropologists were puzzled, because this stance in its essence was part of the bedrock of our discipline, and had been written about and taught for almost a century.

For example, E. B. Tylor, in the first sentence of his 1871 book *Primitive Culture*, strongly hinted at the concept when he wrote, “Culture . . . taken in its wide ethnographic sense, is that complex whole which included knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society” (p. 1). By 1934, when Ruth Benedict wrote her classic *Patterns of Culture*, it was firmly established that

the life history of the individual is first and foremost an accommodation to the patterns and standards traditionally handed down in his community. From the moment of his birth the customs into which he is born shape his experience and behavior. By the time he can talk, he is a little creature of his culture, and by the time he is grown and able to take part in its activities, its habits are his habits, its beliefs his beliefs, its impossibilities his impossibilities. (Benedict, 1934, pp. 3–4)

And Alfred Kroeber, in the 1948 edition of his textbook, the model for all subsequent ones, wrote, “The mass of learned and transmitted motor reactions, habits, techniques, ideas, and values—is what constitutes *culture*” (p. 8; italics in original).

Of course, Vygotsky and his intellectual descendants added much to these generalizations: Concepts such as self-directed (private), then internalized speech, intersubjectivity, scaffolding, and the zone of proximal development served important functions in analyzing the role of the social and cultural context in mental development (Fernyhough, 1997; Wertsch & Sohmer, 1995). These psychological concepts have had great value in specifying more clearly some of the processes of what anthropologists

call “socialization” and “enculturation.” Furthermore, cultural psychology (and not just the developmental kind) came along at the right moment in the history of anthropology. Many cultural anthropologists, including many psychological anthropologists, were smitten by postmodernism, which led some to reject the entire enterprise of the scientific study of culture (Greenfield, 2000). Psychological anthropology stumbled, and the banner of scientific method was largely dropped, just when continued adoption of psychological methods could have had the greatest impact. So it is fortunate that cultural psychology picked up the banner by applying standardized and sophisticated methods cross-culturally.

However, anthropologists have also always recognized that some features of human behavior and culture are universal, have definable evolutionary origins, and may be tied to biology. Other features, although not universal across all cultures, are characteristic of human groups that subsist by hunting and gathering. This means that they may have been needed in the human environment of evolutionary adaptedness, and even though other cultures have departed from them in the course of history, there may be costs to these divergences that are presently unknown. This model, known as “the discordance hypothesis,” posits that in the long course of human evolution our genome formed in response to certain external conditions, and that departures from these conditions may in some cases have been too rapid and extensive for our genes to have responded; thus, there may be a discordance between our current environment and our genes, the latter being not much changed since the hunting-gathering era.

This model has proved very fruitful in evolutionary medicine, which holds that changes in diet, physical activity, and exposure to microbes and parasites have left us with widespread chronic diseases that were uncommon in our remote ancestors (atherosclerosis, diabetes, and asthma, among others). Although it is more speculative to cite changes in social and cultural aspects of the environment as grist for this mill, it is possible that these nonphysical aspects of our ancestral environment have left us with behavioral and psychological characteristics that are not perfectly adapted to current environments.

For example, attention-deficit/hyperactivity disorder (or at least the diagnosis of it) has be-

come endemic in the United States, and we know that it most often comes to light as poor adaptation to school. Some of the features of the disorder, at least in its milder forms, were probably innocuous or even adaptive in our ancestral environments, and although extreme forms of the disorder would be maladaptive anywhere, it is fairly clear that the line between normal and abnormal would be drawn in a different place in a hunter-gatherer culture. Another example might be the consequences of social isolation, which is rare in hunter-gatherer cultures but more common in industrial cultures. Could this change have implications for the prevalence of mood or anxiety disorders? This domain of questions about adaptation and cultural change, and the corresponding approach to human behavior, is the primary subject of this chapter.

SOME RELEVANT HISTORY

The transformation of anthropology during the late 20th century included an increasing focus on large-scale and developed societies, a new emphasis on hearing the voices of the people being studied, recognition of variation within cultures, and an increasingly sophisticated application of quantitative methods (D’Andrade, 1991, 1992, 2001)—even as postmodernist theory has raised questions (sometimes valid, sometimes very exaggerated) about the distortions that such “objectification” of culture and behavior may produce.

Recent decades have also led to a new emphasis on biology as a window on human behavior and culture, not as a strategy for explaining differences among human groups (it cannot) but as an aid to finding common ground among them. As both Alfred L. Kroeber and Margaret Mead, great pioneers in cultural anthropology, recognized by the 1950s, the delineation of cross-cultural variety also inevitably reveals *invariant* features of human behavior and mental life. This proved to be a prescient observation, because the description of universals of language, culture, facial expression, parent-offspring interaction, and many other aspects of human life would soon become possible (D. E. Brown, 1991). These universals constitute a part of what is meant by “human nature,” a term that must be considered again, after decades of disfavor, as having scientific legitimacy (Konner, 2002).

A brief historical review may be useful. In the late 19th century it was not unusual for treatises on aspects of human psychology to refer to ethnographic data. Darwin's seminal book (1998) on the expression of emotion cited the occurrence of certain expressions in primitive societies as evidence for their biological basis and attempted to relate them to emotional expressions in nonhuman animals in an evolutionary sequence. Edward Westermarck, whose theory of incest aversion has survived modern tests (Wolf, 1995), appealed to ethnographic evidence to illuminate a deeper psychodynamic process he considered to be as universal as certain facial expressions. In the late 19th century it was common for prominent anthropologists to attempt to array nonindustrial societies in an evolutionary sequence, whether of social complexity, religion, or language. And in the early years of the 20th century ethnological expeditions tested members of small-scale, nonindustrial societies for the presence of proposed perceptual universals.

These trends, which might be seen as early efforts to characterize human nature and its origins, were transformed by the development of modern social and cultural anthropology and by the parallel emergence of psychoanalysis. Anthropologists came to reject evolutionary sequencing of cultures, replacing this effort with descriptive characterization of cultures as independent units. Proposed universals of human behavior or mental function were met with equal skepticism, and anthropologists to this day delight in the opportunity to say, "Not among my people they don't," a kind of statement that has been aptly called the anthropological veto.

Early generalizations by Piaget and others were tested cross-culturally (Mead, 1932), but none elicited the sort of enthusiasm for such testing as psychoanalysis. The British social anthropologist Bronislaw Malinowski attempted to demolish the universality of the Oedipus complex by describing a separation of male authority (vested in the mother's brother) from the object of male jealousy (the biological father) in "his" society in the Trobriand Islands (an argument persistently debated; Malinowski, 1964; Spiro, 1982). With the skeptical encouragement of Franz Boas, the dean of American cultural anthropology, disciples such as Margaret Mead attempted not only to undermine certain psychoanalytic convictions by means of cross-cultural comparison

(Mead, 1935, 1949) but also to use psychoanalytic and other psychodynamic theory to *explain* culture (Kardiner & Linton, 1939, 1945).

The fundamental theorem of this school was that cultures are distinctive because of distinctive patterns of child rearing, and that a unified approach combining psychoanalysis and cultural anthropology could explain culture and elucidate laws of psychological development simultaneously (LeVine, 2001; Spindler, 1979). During World War II this approach reached its height with speculations about the "national character" of Russians, Japanese, Germans, and Americans, relating them to unscientific observations of infant and child care. Freud's method, difficult at best when applied to a single patient studied for hundreds of hours over several years, was thus adopted for a completely distinct task for which it was clearly not intended.

By the 1950s the approach had generated research that to some extent transcended it through refinement and measurement. Both the assessment of adult psychological disposition and the objective description of child training were made quantitative, the first through projective testing and the second through direct behavior observation, with interview methods supporting both approaches. DuBois (1944) and Wallace (1952) showed through projective testing and interviews that even small-scale, seemingly homogeneous cultures do not have something properly called basic personality (an entity corresponding to the "national character" of large-scale societies). Rather, individual variation in personality and character is great in every known culture, however small-scale or "primitive." At best there is perhaps a "modal personality" shared by a substantial minority of a culture's members (as shown by Wallace for two distinctive Native American groups), and in any case a culture must derive its distinctiveness from the particular mutual articulation of its various personality types, and the opportunities it provides for their expression, rather than from fundamental tendencies shared by a majority—a sort of symphony orchestra model of culture and personality, in which each culture provides a series of scores.

Meanwhile, John Whiting and Beatrice Whiting were trying to place the cross-cultural study of child training on a scientific foundation. A landmark study by John Whiting and Irvin Child (1953) demonstrated that aspects

of childhood experience of interest to psychoanalysts are correlated with certain themes in religion, folklore, and other cultural expressions (which they pointedly called “projective systems”) in a large cross-cultural sample. However, they recognized that such correlations might not imply causality and that childhood experience needed to be measured much more rigorously. The Whitings devoted the next three decades to such measurement in a number of societies around the world and developed a model of the influence of fundamental features of society—such as ecology, economy, and vulnerability to external attack—on child training practices, which in turn might give rise to certain consistent adult predispositions (B. B. Whiting & Edwards, 1988; B. B. Whiting & Whiting, 1975; J. W. M. Whiting, Child, & Lambert, 1966). But it was rarely possible to establish such relationships beyond the level of correlations.

In addition to the Whitings’ work, that of LeVine, Melford Spiro, and others helped bring this strand of psychological anthropology into maturity in terms of both theory and methods (LeVine, 1982, 1998; LeVine et al., 1994; Spindler, 1979; Spiro, 1987, 1999). Overall, the psychological processes of interest to these anthropologists have been those suggested by psychodynamic or personality theory, such as parental behavior, childhood relationships, sex differences, aggression, and nurturance, and they sometimes used cross-cultural studies to challenge prevailing wisdom about these dimensions of behavior (Spiro, 1954, 1979, 1982). It was also sometimes friendly to the overall project of elucidating human nature through the study of cross-cultural differences and similarities in psychological processes (Schlegel & Barry, 1991; Spiro, 1987, 1999).

A parallel development relevant to cross-cultural psychology was the attempt to study systematically the incidence of psychiatric disorders cross-culturally (Murphy, 1976, 1981). This effort was useful but was beset by doubts about the cross-cultural validity of diagnostic categories. Recent attempts to rationalize diagnostic categories at the international and even national level reveal similar obstacles to cross-cultural diagnosis (Summerfield, 2002). Nevertheless three still-valid conclusions emerged from this work.

First, both the general category of psychological deviance and at least several distinct syndromes (depression, bipolar disorder, anxi-

ety spectrum disorders, and schizophrenia) are characteristic of all cultures in which they have been sought (Kleinman, 2003; Murphy, 1976, 1994). These core disorders appear in the face of marked variation in social organization, religious beliefs, gender relations, child-rearing methods, and even of some genetic variation, and appear to be part of the human condition.

Second, although the traditional designation “culture-bound syndrome” is often too strong, some psychiatric disorders in one way or another do appear to be relatively culture-specific. This includes *susto* in Latin America, *amok* in Indonesia, *bikikomori* (social withdrawal) in Japan, *dhat* (semen “loss”) in India, and bulimia (and, to some extent, attention-deficit/hyperactivity disorder) in the United States (Chowdhury, 1996; Keel & Klump, 2003; Levine & Gaw, 1995; Perme, Ranjith, Mohan, & Chandrasekaran, 2005; Sakamoto, Martin, Kumano, Kuboki, & Al-Adawi, 2005; Weller et al., 2002; Westermeyer, 1985). Cultural differences in where the line is drawn between normal and abnormal and between different syndromes may be thought of as “soft” manifestations of the cultural specificity of illnesses. Even if some of the “culture-bound” syndromes are mainly different ways of conceptualizing parts of a cross-culturally universal symptom spectrum, such differences in labeling may be very significant because of the interactive process between symptoms and cognition that plays a role in all mental illness.

Third, given the diagnostic challenges, it is extremely difficult to compare incidence or prevalence of most disorders cross-culturally, much less to draw conclusions about the etiology of hypothesized cross-cultural differences in prevalence. This is particularly true in the developing world, where differential mortality can delete many victims of illness before the survey is done, and in small-scale societies of classic anthropological interest, where the number of individuals suffering any serious mental illness would be expected to be small.

Finally, a separate strand of the psychological approach to culture began rather ignobly, with an attempt to characterize what early 20th-century anthropologists called “the primitive mind.” There was also a belief among psychologists that some contemporary human cultures represented earlier levels of mental functioning, corresponding to alleged earlier stages of mental evolution (Werner, 1948). There was no evidence, but barriers of lan-

guage and cultural differences prevented some psychologists from appreciating the quality and level of mental functioning in nonindustrial cultures. Actual studies of “primitive” language and thought revealed it to be complex and sophisticated (Lévi-Strauss, 1962; Shore, 1996). There is no evidence that different human groups have evolved at different rates, or that any are at earlier stages of physical or mental evolution. In fact, because of the flow of genes among human populations around the world, there has been little opportunity for different human groups to evolve separately (Mayr, 1963; Cavalli-Sforza, Menozzi, & Piazza, 1994). But it took sophisticated methods of cross-cultural cognitive study to establish the complexity of “primitive” thought.

So, two inferences about culture and mind emerged from early 20th century anthropology: First, there is no evolutionary sequence of thought from traditional to modern cultures; second, some basic patterns of human cognition and its development are universal. In addition to universals of language, Franz Boas, Claude Lévi-Strauss, and others posited a psychic unity of the human species and attempted to unveil some of its features. To take one example, Lévi-Strauss (1962) identified a universal dualistic or polarizing tendency in human thought, already studied by Robert Hertz (1960) in the early 20th century and subsequently well demonstrated from ethnological materials subsequently (Almagor, 1989). Dichotomies such as right–left, good–evil, black–white, village–bush, cultured–savage, and us–them typically exaggerate contrasts in what is really a continuum, and this tendency is so widespread cross-culturally as to suggest that a distaste for ambiguity may be inherent in human thought. In the realm of the social, it has been shown experimentally that children and adults embrace the “us against them” dichotomy all too readily (Robinson & Tajfel, 1997; Sherif, Harvey, White, Hood, & Sherif, 1961; Tajfel, 1982).

The late 20th century brought many further changes, both within anthropology and in the emerging field of cultural psychology. Although some cultural anthropologists drifted out of the stream of science, finding their affinities with “postmodern” literary criticism and philosophy (Greenfield, 2000), others became increasingly quantitative, scientific, and to some extent biological (Betzig, 1997; D’Andrade, 1995; Harris, 1968, 1979; John-

son & Earle, 1987; Plattner, 1989; Shore, 1996; Spiro, 1987, 1999). The four subfields of traditional American anthropology—cultural anthropology, archaeology, linguistics, and biological anthropology—became for many anthropologists reunified in an enterprise that had been moribund since the late 19th century: the characterization of human nature, its cultural variety, and its evolutionary origins.

This enterprise advanced on at least eight fronts: (1) the adoption, extension, and testing of evolutionary theory, including applications to behavior; (2) the characterization of human origins in an ever-improving fossil record; (3) the systematic description and analysis of the behavior of nonhuman primates, to test evolutionary theory and to make inferences about the behavior of our ancestors; (4) the study of contemporary and recent hunter–gatherer cultures, with a view toward making inferences about behavior and social organization in the varied environments of human evolutionary adaptedness; (5) the rise of scientific archeology, which reconstructs the demographic and social worlds of past societies; (6) the corresponding attempt by cultural anthropologists to understand ecological influences on contemporary nonindustrial societies; (7) the ongoing documentation of the spectrum of cultural variation; and (8) the characterization of cross-cultural universals of language, nonverbal behavior, and culture.

A very ambitious intellectual program of this kind was proposed by Wilson (1998) in his book *Consilience*, the title of which refers to the merging of different disciplines in a seamless fabric of human understanding. But anthropology, which is inherently interdisciplinary, has a century-long head start on this project. Some cultural anthropologists remain aloof from this unified enterprise, but they admit to being aloof from science as a whole. The many anthropologists who work within it are laying the foundations of a science of human nature (Betzig, 1997; Konner, 2002; Shore, 1996; Sperber, 1996; Spiro, 1987, 1999), whether or not they use the term explicitly, the results of which have proved to be of great and increasing interest to psychology (Barkow, Cosmides, & Tooby, 1992; Buss, 1984, 1989; Cosmides & Tooby, 2000; Crawford & Krebs, 1998; Tooby & Cosmides, 2000).

Cultural psychology, despite its appropriate focus on variation, cannot proceed much further without a deeper understanding of the

evolutionary origins, biological underpinnings, and cross-cultural constants that form the context for this variation. Paradoxically, evolutionary principles are even relevant to the cultural variation itself, not because of cross-population genetic differences, which are minimal, but because some of the cultural variation is canalized by underlying norms of reaction that ensure, or at least promote, adaptation in each of the varieties. Applications of this concept, also called facultative adaptation, to human development have already proved fruitful (Belsky, 1997, 1999; Belsky, Steinberg, & Draper, 1991; Chisholm, 1993; Chisholm, 1999; Hrdy, 1992, 1999).

BIOLOGICAL AND BEHAVIORAL EVOLUTION

The fossil evidence for human evolution has accumulated steadily for 150 years and no one familiar with it doubts the reality and continuity of that evolution. The first specimen recognized as a separate species, a Classic Neanderthal, was discovered in 1856; human-related (hominid) fossils have accumulated at an accelerating rate, and now there are thousands, covering a period of 6 million years. But new discoveries each year change the details of the picture; biochemical taxonomy and, in the last few years, direct taxonomy of genomes have added new dimensions. Controversies remain. It is clear, for example, that the bonobo (*Pan paniscus*) and the common chimpanzee (*Pan troglodytes*) are our closest relatives—each shares more than 98% of our gene sequences—but the behavior of these two species differs markedly, although their estimated time of divergence from each other (1–2 million years ago) is much more recent than that of the human from the ape line (6–8 mya). Chimpanzees are very aggressive, and males markedly dominate females, whereas highly sexual bonobo females assert their relative equality by means of strong coalitions that limit male violence (de Waal, 1989; Wrangham, 1993).

It is also clear that there were more contemporaneous species of hominid than we thought a generation ago, but it is not yet known just how many there were (Wood, 2000; Wood & Richmond, 2000). And it is clear that upright posture was established before most of human brain evolution took place, but the lag between the two, and the role of tool using or tool-

making in brain evolution, remain controversial (Ambrose, 2001). For our purposes, there is no need to resolve these debates, but there is much to be gained from understanding (1) the general higher primate background of human evolution; (2) the environment of human evolutionary adaptedness, that of hunting and gathering; and (3) the principles of evolutionary adaptation as applied to behavior and reproduction. Some propositions in these three categories of knowledge are likely to be relatively insensitive to disruption by future discoveries.

THE HIGHER PRIMATE BACKGROUND

All higher primates (monkeys, apes, and humans) are social animals with great learning capacity, and with the mother–offspring bond at the center of social life (Smuts, Cheney, Seyfarth, Wrangham, & Struhsaker, 1987; Strier, 2000). This bond is prolonged compared with that of most mammals, as are the anatomical and behavioral courses of development, including the lifespan as a whole (Martin, 1990, 1995). Laboratory and field studies demonstrate complex social cognition and social learning, including transmission of social rank, tool using techniques, and knowledge of location of food sources. Play, especially social play, is characteristic of all primate species, particularly during development, and is an important opportunity for learning. The higher primate emphasis on both the mother–infant bond and on play is an intensification of the pattern established by early mammals, and is essential to the understanding of the phylogeny of the limbic system and the emotions (MacLean, 1985, 1993).

Primate groups include a core of genetically related individuals with associated non-relatives. In most instances, especially among the Old World monkeys more closely related to us, that core is matrilineal, stable over the life course of individuals; but in a few species, including our very close relative the common chimpanzee, the core is patrilineal, and the females are unrelated migrants—although here, too, our equally close relative the bonobo takes the matrilineal tack (Strier, 1994). Acts of social support, mutual defense, and generosity are directed preferentially toward genetic relatives (Altmann et al., 1996; Kurland, 1977), and individuals recognize their relatives from

an early age and have a complex cognitive understanding of their relationships (H. Gouzoules & Gouzoules, 1990; S. Gouzoules & Gouzoules, 1987). Despite this bias, monkeys and apes do aid nonrelatives and often receive reciprocal aid in return. Cooperation is ubiquitous, but so is competition, and one of the major purposes of cooperation is mutual defense against members of the same species. Conflict is frequent, with both sexes participating, but with males generally exhibiting more aggression than females (Hrdy, 1981; Wrangham & Peterson, 1996), including sometimes substantial aggression *against* females (Smuts & Smuts, 1993).

Beyond these broad generalizations great variation exists in social organization between and within species. Monogamy is found, although variably, in some South American monkeys and in gibbons, but larger group associations that subsume more temporary associations between individual males and individual females are the rule in most species. Despite orangutans' (*Pongo pygmaeus*) relatively close genetic relationship to humans, the usual social grouping is a lone female with her offspring, living separately from solitary males. In chimpanzees and some New World monkey species, females change groups after puberty, whereas in most others, males change groups, which is a very dangerous process and therefore an opportunity for natural selection. The causes of this variation in higher primate social organization remain uncertain.

Some generalizations may also be made about the nature and social context of individual development among monkeys and apes. Because the New World monkeys separated from the Old World Monkeys and the apes between 40 and 25 mya, some of these generalizations do not apply to all New World monkeys. However, they do approximate the course of development in all the *catarrhines*, a category that subsumes all Old World higher primates, including monkeys, apes, and—with modifications to the developmental pattern—humans. (The rationale for including humans is proposed in the next section.) The *catarrhine* mother–infant complex (Table 4.1) is characterized by a hemochorial placenta, with exceptionally intimate maternal–fetal circulation; singleton birth, with rare and usually unsuccessful twinning; 24-hour physical contact, mainly with the mother, for at least the first few

TABLE 4.1. The Catarrhine Mother–Infant Complex

-
1. Hemochorial placenta
 2. Singleton birth
 3. Twenty-four-hour physical contact in first weeks
 4. Twenty-four-hour proximity until weaning
 5. Nursing more than three times per hour while awake
 6. Night nursing until weaning
 7. Weaning at around 30% of the age of first ovarian cycles
 8. Transition to multiage play group
 9. Variable but low adult male care
 10. Separation from mother → protest, then dejection
 11. Isolation rearing → dysfunctional behavior
-

weeks; staying within a few feet of the mother continuously until weaning; frequent nursing, at least three times per hour, throughout the waking hours; waking to nurse at least once a night for most of the nursing period; late weaning, at around 25–30% of the age at first estrus or menses; gradual transition to a multiage play group; and variable but low involvement of adult males in most species.

In addition, although there are species variations, it may be said that higher primates are generally sensitive to significant perturbations of the early social environment. Mother–infant separations result in protest by the infant, sometimes lasting days, followed by dejection or grief, although in some species, removing the infant from the mother can be much less distressing than removing the mother (Hinde & Davies, 1972a, 1972b; Rosenblum & Kaufman, 1968). More serious and prolonged interventions, such as isolation rearing or repeated, involuntary mother–infant separation, give rise to abnormalities of sexual, maternal, and aggressive behavior that in humans would be viewed as psychopathology (Suomi, 1997, 1999). Furthermore, the extended, direct mother–infant physical contact characteristic of these species may be important to the formation of the relationship (Maestripieri, 2001).

In a number of species, isolation rearing gives rise to stereotyped behavior such as rocking and self-directed aggression, and even deprivation of contact with peers during development has produced abnormal behavior in some experiments. Apparent human analogues of these causal relationships, although difficult to interpret, have encouraged the use of primate models. These primate experiments greatly en-

hance the interpretive value of field studies of higher primate behavior and emphasize the extent to which the normal development of behavior in such animals has come to depend, in the course of evolution, on an intact social matrix.

Natural variation in stable, individual behavior patterns corresponding to personality or temperament occurs in free-ranging monkey and ape groups, and extends to variants that would be considered pathological if seen in humans, such as hyperaggressive, isolative, phobic, or depressed behavior. It is rarely possible to explore the etiology of such variants, but most cannot result from specific abnormalities of social rearing such as the ones deliberately instituted in laboratory experiments. They are probably both genetic and environmental in etiology, and recent research has found an important interaction; rhesus monkeys carrying the short allele of the gene for the serotonin transporter are vulnerable to being reared with peers but without mothers, whereas individuals carrying the long allele show no evident behavioral abnormalities after being reared in this condition (C. S. Barr et al., 2004), a phenomenon with a remarkable parallel in humans (Caspi et al., 2003). (This set of studies comprises the first clear demonstration at the molecular level of the kind of genotype-environment interaction that many psychologists have long proposed.) Some reactions, such as severe depression, as in the case of an 8-year-old wild chimpanzee after the death of its mother, may be incompatible with survival (Goodall, 1986). Others, however, such as hyperaggressiveness (as in the case of two female chimpanzees that systematically and repeatedly killed the infants of other females) may actually enhance reproductive adaptation for the abnormal individual. This theoretical possibility is discussed in greater detail below.

HUNTER-GATHERER ADAPTATIONS

The previous generalizations apply to the social and psychological world of Old World higher primate species for a period of 25 to 40 million years. Against this background, hominids evolved during the last few million years, culminating in the emergence of our species within the last few hundred thousand years, and finally in the appearance of truly modern *Homo*

sapiens about 100,000 years ago (Ambrose, 2001; Cavalli-Sforza & Feldman, 2003).

In the mid-20th century, anthropologists became interested in modeling the circumstances in which our species evolved by reference to studies of extant hunter-gatherers (Lee & DeVore, 1968a). Such studies attempted to document their subsistence ecology and social organization during the limited time in which they were likely to resist modernization. Classical studies included those of Australian aborigines, Eskimo, Amazonian hunter-gatherers such as the Siriono, and many others on all continents (Lee & DeVore, 1968a). More systematic, multidisciplinary, quantitative studies were subsequently done on the Hadza of Tanzania (Hawkes, 1991; Hurtado, Hawkes, Hill, & Kaplan, 1985), the Aché of Paraguay (Hill & Hurtado, 1999), the Agta of the Philippines (Griffin & Estioko-Griffin, 1985), the Efe Pygmies of Zaire (Bailey, 1991; Peacock, 1991), and the Bushmen of South Africa (Lee, 1979; Silberbauer, 1981), among others (Lee & Daly, 1999). These populations have been viewed as representing the environment of evolutionary adaptedness (EEA), although given the variation among them and among the past populations they may represent, the phrase should be pluralized to *environments* of evolutionary adaptedness, or EEAs. The phrase implies that this was the range of contexts for which natural selection prepared us, and from which we have departed only in the past 10,000 years, a very short time in evolutionary terms. (The Industrial Revolution, in the same terms, began just a minute ago.) No one claims that the whole spectrum of EEAs is observable among recent hunter-gatherers, who have occupied only some of the wide range of ecological situations available to our ancestors. However, we also have extensive archaeological, paleodemographic, and paleopathological evidence (Keenleyside, 1998; Reinhard, Fink, & Skiles, 2003) that—with the studies of recent hunter-gatherers—leads to reasonable models of life during human evolution (Kelly, 1995; Winterhalder & Smith, 1981).

From many studies of recent and current hunter-gatherers, combined with archeological evidence of those of the distant past, certain generalizations are possible:

1. Groups were usually small, ranging in size from 15 to 40 people related through blood

- or marriage (but could be larger in ecologically rich settings).
2. They were usually nomadic, moving with changing subsistence opportunities, and flexible in composition, size, and adaptive strategies, although they could be sedentary in richer settings.
 3. Daily life involved physical challenge, vigorous exercise, and occasional hunger, but with a usually dependable food base from a moderate work effort (less than in most agricultural societies), and with a marked division of labor by gender.
 4. Disease, mainly infectious and acute rather than chronic and degenerative, produced high rates of mortality especially in infancy and early childhood, with consequent frequent experience of loss.
 5. Almost all of their life activities occurred in a highly social context with people they knew well—often the same people for different activities.
 6. Privacy was limited, but creative expression in the arts was frequently possible.
 7. Conflicts and problems were dealt with through extensive group discussions, but these did not always work, in which event conflict could escalate to assault and even to homicide.

These generalizations describe the contexts in which almost all of human evolution and history have occurred, so it is often said that we are, in effect, hunter-gatherers in skyscrapers.

However, the environments of evolutionary adaptedness were variable. In some times and places, especially in the last stages of human evolution, populations were larger, denser, and more sedentary (Kelly, 1995). These would probably have afforded the opportunity for social stratification and division of labor, along the lines of the cultures of the Native Americans of the Northwest Coast (Kwakiutl, Tlingit, and others). Such cultures, although based on hunting (including fishing) and gathering, would have prefigured the kinds of social and political arrangements that became common after the advent of agriculture.

In the more basic cultures of human foragers and in some of the more complex ones, whether in the fossil or the ethnographic record, hunting was of major importance. Most of the stone tools that have survived archaeologically were used in hunting or butchering,

and the demands caused by this activity have long been held to be central to the emergence of human intelligence and social organization (Lee & DeVore, 1968b; Stanford, 2002). Some stone used for this purpose had to be traded over long distances, implying unexpectedly complex social networks among our ancestors 2 million years ago. Furthermore, even chimpanzees share meat after a kill (but not plant foods), and among human hunter-gatherers, following elaborate regulations for such sharing of meat may have been a life-and-death matter. Finally, with one important exception (the Agta of the Philippines, where women routinely hunted) all hunting and gathering societies in the ethnographic record had a division of labor by sex, with men doing almost all the hunting and providing meat for women and children, and women providing most of the plant foods. For these reasons, among others, it is believed that some peculiarly human aspects of social life are due to the advent of hunting but were grafted onto an already complex social life characteristic of nonhuman higher primates.

However, this is at most half of the story (Dahlberg, 1981). In many hunting and gathering societies, plant foods gathered by women constituted much more than half of the diet. Plant foods were shared in these societies (although not beyond the immediate family), whereas they were not shared in nonhuman primates. Postweaning mortality is much higher in nonhuman primate juveniles than in human children, and it has been suggested that the provision of children with plant foods by human mothers accounts for this difference (Lancaster & Lancaster, 1983) and that the long postreproductive life of human mothers is what allowed not only this process but the so-called “grandmother effect,” in which postmenopausal women serve the same function for their grandchildren (Hawkes, O’Connell, & Jones, 2003; Hawkes, O’Connell, Jones, Alvarez, & Charnov, 1998). Even the early advent of upright posture may have had more to do with women’s need to carry plant foods, as well as infants, to a base camp than with any advantage upright posture conferred in hunting, and it may be that among the first tools invented were digging sticks and carrying devices for plants or infants—tools that, however crucial, would not be preserved in archaeological assemblages and would most likely have been

invented by women (Tanner, 1987; Zihlman, 1981).

Baby and child care were also distinctive in such societies (Konner, 2005) although there were significant variations (Blurton Jones, 1993; Griffin & Estioko-Griffin, 1985; Hewlett, 1991; Marlowe, 2005; Tronick, Morelli, & Ivey, 1992) and included the following: (1) frequent breast-feeding (up to four times an hour); (2) late weaning (at least age 2, and up to age 4); (3) close mother–infant contact, including extensive skin-to-skin carrying and adjacent sleeping until weaning; (4) prompt response to infant crying and indulgent response to other infant and child demands; (5) the opportunity for maternal primacy in attachment; (6) more father involvement than in most societies; (7) a gradual transition from an intense mother–infant bond to a multiage mixed-sex play group; (8) usually less assignment of responsibility in the sense of chores or formal education in middle childhood, with learning taking place through observation and play; (9) liberal premarital sexual mores compared with non-hunter–gatherers, with sex play in middle childhood gradually giving rise to adolescent sexuality; (10) late menarche, limiting opportunities for childbearing until the late teens or early 20s. These generalizations about hunter–gatherer infancy and childhood have withstood the test of time and of excellent new research in at least five hunter–gatherer societies (Konner, 2005).

Humans, like Old World monkeys and apes, are catarrhines, but they can only be included in the catarrhine mother–infant complex if the mother–infant relationship in the human EEAs conforms to it, because departures are very evident in other ecological settings. The question of whether the mother–infant relationship in the EEAs can be subsumed under the general catarrhine model hinges in turn on the validity of the hunter–gatherer childhood (HGC) model already discussed. Unlike the catarrhine mother–infant complex (CMIC), this model goes substantially beyond infancy. Table 4.2 lists the main features of the HGC model as originally proposed (for references, see Konner, 2005).

Each feature of the model was originally derived from observations of the !Kung, supported by descriptive accounts of other hunter–gatherers in the older ethnographic literature. The generalizations were presented as hypotheses for further study, in the hope that others

TABLE 4.2. Features of !Kung Infancy and Childhood: The First HGC Model

1. Prolonged close physical contact with the mother
2. High indulgence of dependent needs and demands
3. Frequent nursing (four times per hour) throughout waking hours
4. Mother and infant sleep on same bed or mat; night nursing
5. Weaning after age 3 and 4-year birth spacing ^a
6. Strong separation and stranger protest until late ages ^b
7. Dense social context that seems to reduce pressure on mother
8. Nonmaternal care much less than maternal care until second year ^a
9. Paternal care much less than maternal care, but more than in most cultures
10. Transition to multiage, mixed-gender child play group
11. Minimal childhood responsibility for subsistence or baby care ^a
12. Minimal restrictions on childhood or adolescent sexuality

^a An important challenge comes from new research.

^b There is too little information in other studies to generalize.

would do serious HGC research. This hope was realized, and subsequent studies have been excellent.

New quantitative studies have focused on infancy and childhood in at least five hunter–gatherer cultures: the Hadza, the Efe, the Aka, the Aché, and the Agta. Each of these groups has been described as departing in one way or another from the HGC model as originally presented based on studies of the !Kung and reviews of older literature on other hunter–gatherers (Konner, 1981). We can now place these departures in context with a systematic comparison.

Table 4.3 (Konner, 2005) shows the findings of recent studies regarding key features of the HGC model, suggesting a high level of support for most of the original generalizations: frequent nursing, mother–infant cosleeping, high physical contact, high overall indulgence (possibly excepting the Hadza), substantial to high nonmaternal care and father involvement, maternal primacy, transition to a multiage child group, a relatively carefree childhood (except the Hadza), low restriction of premarital sex, and strong adolescent initiation rites. Only the Aka match the !Kung in age at weaning and

interbirth interval, but the other three cultures have weaning ages over 2 years and interbirth intervals over 3 years. This is at the upper end of the range for nonindustrial cultures and sustains the generalization that hunter-gatherers have relatively late weaning and long birth spacing.

However, the HGC model does represent an important departure from the CMIC. Two- or even 3-year birth spacing is not 25–30% of the age at female sexual maturity, which in hunter-gatherer societies (and most other traditional cultures) is about age 16. The great apes may in fact depart in the other direction from the basic catarrhine pattern, nursing until age 4 or 5, with a female age at sexual maturity of 9. The shortening of the length of nursing is one of the key changes in human evolution, making possible more rapid population growth; it is in turn made possible by the practice of postweaning provisioning, unknown in other primates (Hawkes et al., 1998; Lancaster & Lancaster, 1983). In hunter-gatherers, as in nonhuman carnivores, meat is offered to children after or even before weaning. However, human hunter-gatherers also provide children with plant foods appropriately prepared as weaning foods; despite the long and solicitous mother-offspring relationships that occur in all catarrhines, providing the young with food occurs only in humans.

To place these generalizations in a broader phylogenetic context, the care of infants and juveniles in Old World monkeys and apes (in

contrast to that of human hunter-gatherers) is characterized by not only (proportionately) somewhat later weaning age and interbirth interval but also by variable and species-specific importance of nonmaternal care, minimal father involvement except in gibbons, the absence of postweaning provisioning (the basis of a relatively carefree childhood), mixed-sex play groups that may be same-age groups in seasonal breeders, and the absence of initiation rites. But other HGC features *are* present in most higher primates, including frequent nursing, late weaning, mother-infant cosleeping, high overall indulgence, maternal primacy, and adolescent sexuality. The wide distribution of these features in monkeys and apes suggests that they are common features of the catarrhines and may have been present in the common ancestor, which lived between 30 and 40 million years ago (Martin, 1990).

However, although it is not strictly a part of child rearing, the great majority of hunter-gatherer children experienced loss and grief through the death of siblings, parents, or other loved ones, and many had life-threatening illnesses themselves. Largely because of morbidity and mortality, the hunter-gatherer pattern of childhood experience was far from idyllic, although frustration and loss came mainly from inadvertent features of the environment rather than from parentally imposed stresses. Still, physical punishment and ridicule were occasionally used by parents among the !Kung (Shostak, 1981), children were required to for-

age for themselves among the Hadza (Blurton Jones, 1993), and the experience of loss was virtually universal.

As for the outcome of these child care practices, we cannot infer causality, but the limits of any protective effect are suggested by the fact that both major and minor mental illnesses were present in such societies, and that all of them experienced some level of violent conflict up to and including homicide, which may have exceeded levels in American cities in some groups (Lee, 1979). Normal human behaviors usually considered undesirable, such as selfishness, deceit, adolescent rebellion, adultery, desertion, and child abuse, occurred in such societies, although it is impossible to compare the rates of such behaviors to those in large-scale industrial states. Although fluid and flexible in many ways, life in such societies was restricted to a much smaller number of people than in our own, and the lack of privacy and inability to get away from those people could have been stressful, just as crowding and high levels of contact with strangers may be stressful for us. (Relationship problems tended to be everybody's business, discussed at length around the fire at night, and it may not be far from the truth to consider much of the Paleolithic—at least after the evolution of language—one interminable encounter group.) And, of course, the stresses of morbidity and mortality, as well as the stresses and uncertainties of the daily food quest, must have taken their toll. It is possible that the very common generalized anxiety disorders of our present world are the evolutionary legacy of a world in which mild, recurring fear was adaptive (Nesse & Lloyd, 1992).

War was rare or unknown in hunter-gatherers in recent generations, although ambushes did occur, and deadly intervillage raids are described in some historical material. Conflicts were often resolved by the sharing of food and other goods, and by talking well into the night, sometimes for weeks on end. Few social or economic distinctions were known, nor could they be maintained, because the ethic of sharing strongly pressured a person to part with any accumulated wealth as soon as such wealth became visible (Wiessner, 1982, 1996). Stinginess was in general a serious offense, punished by social ostracism; in cultures where mutual aid is central to survival, no one can suffer ostracism for long. However, ample evidence suggests that in times and places where the food base was rich enough to allow higher

population densities (e.g., the cultures of the northwestern United States and western Canada), economic distinctions and social stratification did emerge.

CROSS-CULTURAL UNIVERSALS OF HUMAN BEHAVIOR, MIND, AND CULTURE

We have considered what may be distinctive about psychological aspects of culture among recent hunter-gatherers, with a view toward establishing a baseline of adaptations characteristic of our species in its environments of evolutionary adaptedness. Although these features are arguably more “natural” than those in other cultural adaptations, and departures from them could conceivably have interesting psychological consequences, they do not have the more privileged status of cross-cultural universals, which are more likely to reflect underlying biological tendencies. Although the main enterprise of cultural anthropology in general and of psychological anthropology in particular, as well as of cultural psychology, has been the description and analysis of cross-cultural variation, that enterprise has always had an inevitable, if tacit, complement: characterizing features of human behavior that vary relatively little or not at all.

The concept of universals has, however, at least five different meanings: (1) behaviors, such as coordinated bipedal walking or smiling in some social greetings, that are exhibited by all normal members of every known society; (2) behaviors that are universal within an age or sex class, such as the Moro reflex in all normal neonates or the muscle contraction patterns of orgasm in all postpubertal males; (3) central tendencies that apply to all populations but not all individuals, such as the sex difference in physical aggressiveness; (4) universal features of culture rather than of behavior, such as taboos against incest and homicide, the variable but always present institution of marriage, or the social construction of illness and attempts at healing; and (5) characteristics that, although unusual or even rare, are found at some level in every population, such as homicidal violence, thought disorder, depression, suicide, or incest.

The list of characteristics that fill these five categories is a very long one, much longer than the prominent anthropologists of the early heyday of cross-cultural study might have pre-

dicted. It includes remarkable constancies in not only nonverbal communication (Eibl-Eibesfeldt, 1971, 1989) and its interpretation (Ekman et al., 1987; Ekman & Rosenberg, 1997), and the semantic domains of words used to describe basic emotions (Heider, 1991), but also in social arrangements and many features of culture (D. E. Brown, 1991). The search for societies that have no violence, no gender differences that go beyond childbearing, or no mental illness, or that lack basic skills, such as making and using effective tools and fire, has been a vain one. Although there is convincing documentation of variation in the incidence or context of expression of most human behaviors, the existence of such a large core of constantly present, if variable, features constitutes a demonstration of the reality of human nature and its validity as a scientific construct. These universals are fundamental to the nature of our species in a deeper way than the features found in human hunter-gatherers and from which later forms of society departed; universals are found in all societies regardless of environment or subsistence ecology, and thus may be intrinsic to human nature.

Traditional cultural anthropologists frequently have shown little or no interest in such universals, viewing them as trivial or outside

their subject matter, but the elucidation of universal features of human behavior and culture is increasingly being recognized as a central task of the discipline, and one likely to enhance the study of cultural variation. Some cultural anthropologists—most prominently Claude Lévi-Strauss—have attempted to delineate such universals as symbol systems and mental structures whose common underlying characteristics link widely disparate surface manifestations in art, language, and ritual (Lévi-Strauss, 1962, 1963; Shore, 1996). This intellectual strategy owes much to that of comparative linguists, who have found a variety of common functional features of all languages that transcend their specific manifestations (C. H. Brown & Witkowski, 1981; Chomsky, 1988; Comrie, 1989).

A model of the role of phylogeny and its consequences for human nature in the generation of cross-cultural differences is shown in Figure 4.1. It is based on a model presented by B. B. Whiting and J. W. M. Whiting (1975), which did not include an explicit role for phylogeny but did recognize a universal course of psychological development at the center of the psychocultural dynamic. It also gave a privileged place to the ecological situation of cultures in shaping their psychosocial realities;

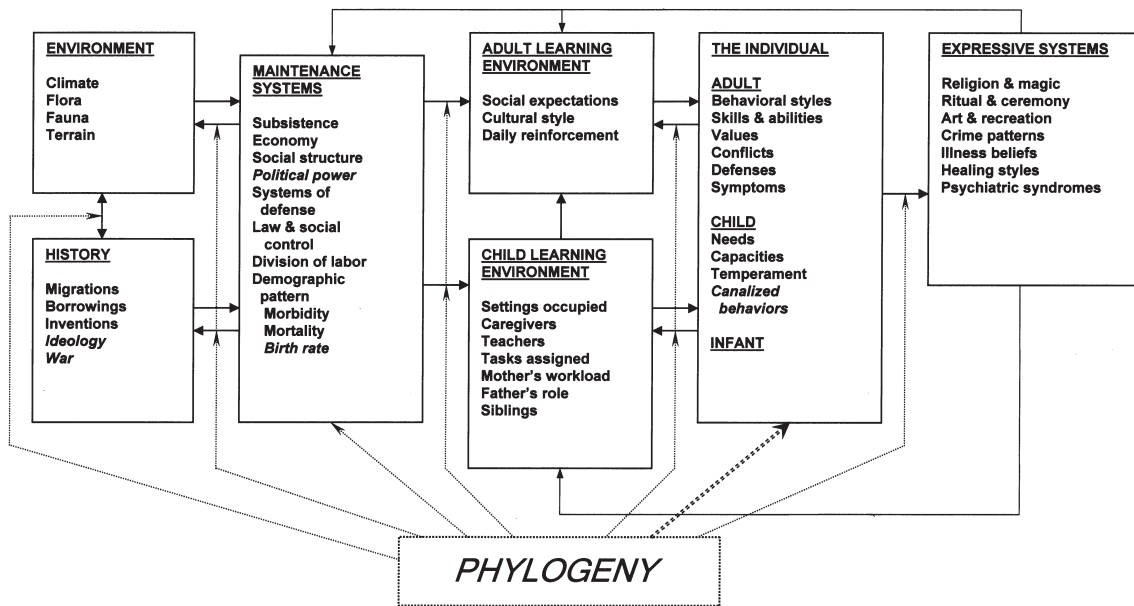

FIGURE 4.1. A model of the influence of phylogeny on psychocultural adaptations. Modified from Whiting and Whiting (1975). Substantive additions are italicized.

that is, it took what anthropologists would call both a materialist and a functionalist position, arguing that people and cultures must adapt to ecological circumstances in historical context, and that cultural psychology is best understood as an adaptation or consequence of other adaptations. In this model, history and culture are not driven by ideas; rather, ideas emerge as part of human responses to situations and needs. However, this modified version of the model does contain more feedback than the Whiting model, which relied almost entirely on unidirectional causal flow.

The modified version suggests that describing universal features of human behavior is central to understanding the effects of phylogeny, which are shown in dotted lines in the diagram. Phylogeny is shown directly to affect one of the boxes, that representing the individual—not only the “innate needs, capacities, and temperament” but also the relatively fixed elements of cognitive and psychosocial development. But most phylogenetic effects on the system are modeled as occurring through evolution’s influence on other arrows; that is, natural selection operating on organisms ancestral to ourselves created not only individuals with certain needs, capacities, temperaments, and canalized maturational plans, but also equations—if . . . then . . . statements—relating the environment to the social system, the social system to the individual, and so on. These are the facultative adaptations familiar to evolutionary biologists that set limits on plasticity by guiding the organism’s responses to environmental variation: plasticity, yes, but canalized plasticity.

Referring again to the example of husband-wife intimacy (J. W. M. Whiting & Whiting, 1975), phylogeny appears to have given us a system such that separating men from women and small children enhances men’s effectiveness as warriors. This is not to say that men must be warriors or that they must be aloof from their wives, but that choosing aloofness may increase effective belligerency, and/or that the reverse may be true. The universal feature here is not a phenotypic characteristic, but an underlying mechanism relating two phenotypic continuums to each other. This example (irrespective of its empirical validity) clearly shows that a Darwinian explanation of a social adaptation is fully compatible with a psychological explanation of its development, the latter serving as the means to achieve the adaptation in

our long-lived, slowly growing, highly cultural species. In recent years Darwinian theory has been extended to encompass this possibility, in which a particular causal relationship between childhood experience and adult behavior *is* the adaptation (Belsky, 1997, 1999; Belsky et al., 1991; Chisholm, 1993, 1999; Hrdy, 1992, 1999).

In the past few decades the application of neo-Darwinian or sociobiological theory to ethnological materials has produced some findings that at first glance seem to bypass complex questions of the relationships among society, culture, and individual development (for a helpful critique, see Symons, 1992). For example, societies in which young men inherit land from their mothers’ brothers are more lax about the control of women’s sexuality than are those in which young men inherit from their fathers (Hartung, 1982); in societies that allow polygyny, wealthier men tend to have more wives, the extreme being despots with as many as hundreds (Betzig, 1986, 1992); and in small-scale societies in which adoption of children is common, it tends to follow patterns predicted by genetic relatedness (Silk, 1980, 1987). Investigators making these findings usually do not claim any direct genetic basis for these variations in human cultural practices; indeed, some of the most unfortunate confusion stems from a failure to appreciate this distinction between the propositions of neo-Darwinian theory and those of behavioral genetics.

Even in a nonhuman species such as the red-winged blackbird, males singing on richer territories mate with several females instead of one. But the mechanism of this flexible adaptive system—an example of facultative adaptation—may be quite different in blackbirds than that of the functionally parallel flexibility in human beings. The wings of insects come from thorax, the wings of birds from forearm structures, the wings of bats from fingers, and the wings of humans from technology. These four solutions to the adaptive challenge of flight serve similar functions with extremely different points of origin. The same will prove to be true of subtler adaptations in social behavior.

For example, evolutionary psychologists (like classical evolutionists and geneticists before them) predicted that incest would be avoided in most sexually reproducing species to prevent maladaptive homozygous recessive conditions. But adults seeking mates must

recognize close kin. In insects, and in some vertebrates, such recognition depends on pheromones (L. Greenberg, 1979; Manning, Wakeland, & Potts, 1992), but the unlikelihood of that mechanism in humans has led to a search for other ontogenetic explanations. The anthropologist Arthur Wolf, motivated more by psychological than evolutionary considerations, has shown conclusively that in traditional China, where young girls sometimes live with the families of their intended spouses (also still children), the resulting marriages had a much higher rate of failure and infertility than did other arranged marriages, and has also identified a sensitive period of contact required for the effect (Wolf, 1995). Similar findings emerge from studies of the marriage rate among Israeli kibbutz cohort members (Shepher, 1971).

These studies support the “familiarity breeds contempt” hypothesis of incest, first introduced by Edward Westermarck in the 19th century. The implication is that human beings achieve inbreeding avoidance through a psychological mechanism partly dependent on cultural choice, even though the evolutionary effects (the adaptation) may ultimately be functionally equivalent to those in species that rely on pheromones for their own incest avoidance. In analyses such as these, the purposes and methods of cultural anthropology, cultural psychology, and evolutionary psychology are joined, and the study of human behavior in general is much better served than it is by sterile debates about nature and nurture.

UNIVERSALS AND VARIATIONS IN PSYCHOSOCIAL GROWTH

Freud postulated, and present-day psychodynamic psychology continues to accept in altered and disputed forms, a universal sequence of emotional development upon which the social dynamic of the family was said to produce enduring emotional traits. Beyond some very general elements—the formation of an attachment to a primary caregiver who is usually the mother, for example, or the ubiquity of conflicts and jealousies within the family—this hypothesized universal sequence has found little empirical support. But cross-cultural studies of human behavioral and psychological development have produced extensive evidence supporting some different, more empirically

grounded proposed universals of psychosocial growth. In the absence of knowledge of neuropsychological development, psychoanalytic theory postulated a crude libidinal theory of neural development. Now, the growing body of knowledge of neural and neuroendocrine development can begin to serve a parallel function in relation to the more empirically supported, newer studies of psychosocial growth.

Among the well-established cross-cultural universals of psychosocial development, the following are the best supported and can in most cases be plausibly related to possible underlying neural or neuroendocrine maturation:

1. The emergence of sociality, as heralded by social smiling and mutual gaze, between 2 and 4 months of age, in parallel with the maturation of basal ganglia and cortical motor circuits (Konner, 1991; Yakovlev & Lecours, 1967).
2. The emergence of strong attachments, as well as of fears of separation and of strangers, in the second half of the first year of life (van IJzendoorn & Sagi, 1999), in parallel with the maturation of the major fiber tracts of the limbic system (Konner, 1991; van IJzendoorn & Sagi, 1999).
3. The emergence of language during and after the second year (Bates & Marchman, 1987), in parallel with the maturation of the thalamic projection to the auditory cortex, among other circuits (Lecours, 1975).
4. The emergence of a sex difference in physical aggressiveness in early and middle childhood, with boys on average exceeding girls (Maccoby, 1998; B. B. Whiting & Edwards, 1988), a consequence in part of prenatal androgenization of the hypothalamus (Collaer & Hines, 1995).
5. Growth beyond the emotional lability of early childhood in the 5- to 7-year shift, with its major cognitive advances including advanced perspective taking, concrete operations, and metacognition, enabling years of complex enculturation (Rogoff, Sellers, Pirrotta, Fox, & White, 1975; White, 1970, 1996), a transition that may be due to the peak of both synapse number and brain metabolic rate in this age range.
6. The onset of adult sexual motivation and functioning in adolescence (Schlegel & Barry, 1991), in parallel with and following the maturation of the hypothalamic-

pituitary–gonadal axis at puberty (Ebling, 2005; Halpern, Udry, & Suchindran, 1997, 1998), against the background of the prenatal androgenization of the hypothalamus, as well as continuing maturation of brain white matter (Paus et al., 2001).

There are other likely cross-cultural developmental universals, such as the rise and fall of distress crying over the first 3 months (R. G. Barr, 1990; R. G. Barr, Konner, Bakeman, & Adamson, 1991), increased babbling in the second half of the first year (Locke, 1989), the attainment of the false-belief task at approximately age 4 (Callaghan et al., 2005), and progress through the first three or perhaps four of the six stages in Lawrence Kohlberg's scheme of moral development in childhood (Edwards, 1981). But these are neither as well established nor as plausibly related to underlying maturational events as are the six universals proposed earlier. Although their underlying neurobiology is at an early stage of elucidation, their cross-cultural universality is well established, and there is in each case extensive experimental evidence to support the maturational nature of the process in behavioral development. Thus they constitute a first approximation of the true structural basis of psychosocial development.

They also constitute a basis for future understanding of how variations in social experience interact with maturing psychosocial competence to produce potentially stable variations. In each of the six processes mentioned, cross-cultural differentiation of the maturing competence begins almost as soon as the maturation occurs, or even during the maturation process itself. In some cases there is sufficient evidence to state provisional rules relating environment to differentiation, for example, "Infants whose smiles are favorably responded to will smile more" or "All children will acquire languages with similar cognitive and social functions, but with whatever arbitrary semantic content is presented, and with much less arbitrary variation in syntactic features." In others, such as the differentiation of the strength, duration, and multiplicity or exclusiveness of attachment in different cultures, it has been difficult to demonstrate causal relationships to the characteristics of the social and emotional world that preceded the attachment. Thus, some important developmental events and trends remain refractory to explanation, whether biological,

psychological, or cultural. However, the acceptance and increasingly detailed and reliable description of the maturational constants underlying cultural variations in psychosocial growth will provide a steadily firmer place on which to stand while attempting to grasp the role of cultural and individual experience.

NEO-DARWINIAN THEORY OF BEHAVIORAL ADAPTATION

Since the late 1960s an influential new field of evolutionary study has emerged, known variously as *neo-Darwinian theory*, *evolutionary psychology*, *Darwinian social science*, or *sociobiology*, although these names are not exact equivalents. It has been quickly adopted by most investigators who study animal behavior under natural conditions and has also influenced many anthropologists and psychologists. Briefly summarized, the principles are as follows.

1. An organism is a gene's way of making another gene (Dawkins, 1978, 1989). More strictly, it is a way thousands of cooperating genes make copies of themselves. If nature is physicochemical, then continued membership in an ongoing genetic line is the ultimate purpose served by any gene. To the extent that a gene influences behavior, it can only continue in the line if it maintains or enhances, through the behavior, the number of copies of itself in the next generation's gene pool.

2. Genes persist or increase by enhancing reproductive success. Where survival and reproductive success are in conflict, reproductive success prevails. "Fitness" in evolutionary theory means only the relative frequency of genes (Lewontin, 1974). It is a tautological dimension of reproductive success and has nothing necessarily in common with medical, social, or athletic definitions of fitness, all of which can be achieved without an increase, or even with a decrease, in technically defined fitness.

3. Fitness is *inclusive*, meaning that genes influence their frequency through not only the reproductive success of the individual carrying them but also that of close relatives who may carry the same gene through common descent. This is the concept introduced by W. D. Hamilton (1964) using the mathematics of evolutionary genetics, to account for the altruism in ani-

mals, which previously seemed as if it should be culled by natural selection (1964). It led to a newly defined subprocess of natural selection, *kin selection* (Dawkins, 1979). If I die to save my identical twin, then the frequency of any gene that helped predispose me to that action will (all else being equal) be unaffected by my death. In general terms, genes predisposing me to self-sacrifice for a relative, should be favored when $b/c > 1/r$, where b is the benefit to the recipient, c the cost to the altruist, and r the degree of genetic relatedness, or likelihood that a gene is found in two individuals by common descent. This helps explain the self-sacrifice of soldier ants, the alarm calls of birds and ground squirrels, and nepotism in human beings, among other phenomena. Other theories bearing on the problem of altruism are reciprocal altruism (Trivers, 1971) and the prisoner's dilemma model of cooperation (Axelrod & Dion, 1988; Axelrod & Hamilton, 1981), neither of which requires that the altruist and the recipient be related.

4. As argued by Trivers based on an observation by Darwin, in species with two sexes that differ in the energy invested in offspring, the sex that invests more is a scarce resource over which the other competes (Trivers, 1972). In mammals and in most birds, females invest more, but direct male parental investment is very high in some species. Species in which investment is high tend to have long-lasting pairing of a breeding male and female, and low levels of sexual dimorphism, male-male competition for females, and male variability in reproductive success. These pair-bonding species, including 8,000 species of birds but only a few mammals, may be contrasted with so-called "tournament" species, in which there are annual seasonal breeding events where males compete intensely for females. These species often have high sexual dimorphism for fighting or display (e.g., antlers and peacock feathers), low levels of pair formation and male parental investment in offspring, and high variability in male reproductive success. Human beings are near but not at the pair-bonding end of the continuum, as indicated by sexual dimorphism, degree of direct male involvement in child care cross-culturally, and the known distribution of human marriage forms (Daly & Wilson, 1983). Polygyny (one man marrying two or more women) is allowed in most cultures in the anthropological record (708 of 849, or 83%), whereas the converse, polyandry, is rare (4 of

849), and a double standard of sexual restriction is common (Murdock, 1949). Still, most human marriages have probably been monogamous, at least in intent.

5. A neo-Darwinian model of parent-offspring conflict (Trivers, 1974) has important implications for the nature of the family. Weaning conflict is common in mammals, and equivalent phenomena among birds even include tantrum behavior. If the evolutionary purposes of mother and offspring were identical, then they would "agree" (shorthand for "would have been selected to act as if they agreed," not implying conscious intent) that a given level and duration of investment is necessary and sufficient, after which the mother should produce another offspring. However, the offspring's gain will be two or four times as great (depending on whether the siblings share a father) if it acts selfishly. Eventually the offspring's diminishing need is outweighed by the inclusive fitness advantage gained through the sibling's birth, but this comes later for the offspring than for the mother.

6. Competition among unrelated individuals can be extreme (Daly & Wilson, 1988). Almost all adequately studied animal species exhibit violence, up to and including killing, in the wild. One particularly noteworthy phenomenon is competitive infanticide, already alluded to in chimpanzees. The paradigmatic case is the Hanuman langur monkey of India, *Presbytis entellus* (Hrdy, 1977). Langur troops comprise a core of related females, their offspring, and unrelated males, sometimes challenged by new males. If the new males drive the previous ones away, they systematically kill all infants under 6 months of age. The mothers then come into estrus again, much sooner than if they had continued to nurse, and are impregnated by the new males. Controversy over whether this is normal behavior or a response to crowding or other stress misses the point: It enhances the reproductive success of the new males at the expense of the old, and so can be expected to be favored by natural selection, whether or not we call it "normal." Life and evolution are stressful, and responses to stress determine ultimate outcomes. Similar phenomena have been observed in many species (Hausfater & Hrdy, 1984).

Overall, these principles necessitate rejection of a naive model of the family, which assumes that it functions as a harmonious unit under

ideal conditions. It was not so designed and is instead an association of individuals with overlapping but distinct evolutionary interests. Its members naturally pursue goals that are sometimes at odds with each other’s ultimate purposes, and their relations are naturally conflictual rather than harmonious. Rather than being the result of friction in what should be a smoothly functioning system, much conflict is intrinsic.

This is even truer of communities, societies, and cultures, each of which is a collection of individuals, families, and larger kinship units engaged in short- or long-term cooperation for the pursuit of individual and inclusive fitness goals. If it is true that societies or cultures as a whole are adapted (Harris, 1979, 1997), limits to this collective adaptation are imposed by individuals and kin groups that take advantage of the collective, favoring their own inclusive fitness. The well-known “tragedy of the commons” is only one example. Cultures with slaves, castes, hierarchies of ethnic groups, racism, sexism, and even mere social classes may be in some sense adapted *as cultures*, because they are surviving and reproducing, but such cultures enable some groups to enhance their reproductive success at the expense of others. These arrangements may be stable over time, but that does not make them adaptive for all members of the culture. Furthermore, this statement is true of not only cultures that encourage competition (e.g., the United States) but also those that encourage cooperation (e.g., Japan), although the mechanisms of exploitation may differ greatly.

A CULTURAL ACQUISITION DEVICE

Despite human universals and guided adaptations, and in part because of them, the particulars of culture invade and affect the developing mind. But how?

This question is best answered by reference to a much broader range of psychological processes than is conventionally considered by cultural psychologists. The acquisition of culture, like the acquisition of language, is basically a human adaptation, protocultural (and protolinguistic) achievements of other animals notwithstanding. But if there is a language acquisition device (LAD), as proposed by Chomsky, Lenneberg, and others, it remains quite mysterious. The cultural acquisition device (CAD),

on the other hand, comprises elements that are fairly well understood by psychologists and anthropologists. A proposed version of the CAD is presented in Table 4.4.

The CAD consists of 17 processes loosely divided into four categories; the italicized processes are probably unique to the human species. The first category, reactive processes, comprise the most basic mechanisms of behavior modification that occur inevitably in growing up in a certain context (J. W. Whiting, 1941). The second, facilitative processes, includes social processes that rely on intersubjectivity, the ability to take the perspective of the other, at least in one direction. The third, emotional enculturation, includes processes that are inherently based on strong emotions designed by evolution to shape behavior. The fourth and last category, symbolic processes, rests on uniquely human capacities for the formation of symbols and their integration into culturally significant schemas. Brief definitions of the processes follow.

TABLE 4.4. A Proposed CAD

Reactive processes (cultural habitus)
Habituation (response decrement)
Classical conditioning (including emotions)
Associative conditioning (perceptual learning)
Instrumental conditioning (cultural selection of actions)
Social facilitation (relaxation of inhibition)
Facilitative processes (social learning)
Local enhancement (ad hoc scaffolding)
Imitation (nontargeted modeling)
<i>Instruction (Contingently responsive scaffolding)</i>
<i>Collaboration (Co-construction of knowledge)</i>
Psychodynamic processes (emotional enculturation)
Attachment (recruitment for socialization)
Positive identification (focused modeling)
Fear of strangers (the comfort of the familiar)
Negative identification (us–them polarization)
<i>Emotion management (the comfort of ritual)</i>
Symbolic processes (cognitive enculturation)
<i>Cultural construction of perception (collective assimilation)</i>
<i>Cultural schematization (collective accommodation)</i>
<i>Narrative construction (narrative meaning)</i>
<i>Cultural coherence (overarching themes)</i>

Note. Freely adapted from theoretical discussions in Whiting (1941), LeVine, (1982), Tomasello, Kruger, and Ratner (1993), and Shore (1995). Processes unique to humans are italicized.

Reactive Processes (Cultural Habitus)

Habituation

Habituation, or response decrement, is a classic ethological concept referring to a usually adaptive waning or disappearance of an inborn response that is repeatedly elicited by the environment without serving a function. For maturational reasons 8- to 10-month-olds show wariness of strangers, but in American culture, with its high frequency of encounters with strangers, the response wanes over weeks to months, whereas in !Kung culture, where strangers are rare, it does not.

Classical Conditioning

Children are bathed in stimuli that occur in association with a much more restricted initial group of unconditioned stimuli, linked through innate neural circuits to reflexive responses. Suppose that the calming effect of being held by a calm mother is innate. If being in church calms the mother, then this setting will gain the power to calm the child, because the unconditioned stimulus (calm mother) becomes associated with conditioned stimuli such as liturgical music.

Associative Conditioning

This ubiquitous process engrains expectations as to the spatial and temporal contiguity of stimuli, and so establishes patterns or schemas even in the absence of action. In Samoa, a welcoming ritual places an orderly set of sights, sounds, actions, and utterances before a child, who does not need to participate to learn the pattern.

Instrumental Conditioning

In all societies some naturally occurring behaviors are rewarded (reinforced), and others are punished. From infancy !Kung children are socially rewarded for sharing, a fundamental cultural value and pattern, but punished for approaching a fire, and the behaviors wax or wane, respectively.

Social Facilitation

A child observes others performing an action for which there is a tendency already present, but which is released from inhibition by the ob-

servation, the simplest example being yawning. This is probably the main process involved in the acquisition of culturally specific dietary patterns.

Facilitative Processes (Social Learning)

Local Enhancement

In a kind of “scaffolding,” or enhancement of the child’s opportunity to learn, the ordinary course of events in the life of one individual of necessity brings the child into situations that make learning by trial and error easier. A berry-picking expedition, for example, brings a child into a setting where the reward of eating berries and the punishment of encountering thorns shape the child’s behavior.

Imitation

This general process by which observing another’s behavior allows the child to shorten greatly the time required for learning by matching the actions and/or the goals of the other does not necessarily require a relationship or an identification (see below), but it does require the child to take the perspective of the other. It differs from social facilitation in that it is not an internally driven response under inhibition before the observation.

Instruction

Unique or almost unique to humans, instruction involves *intersubjectivity* (Tomasello et al., 1993); not only must the child take the other’s perspective but the other must also take the child’s and engage in deliberate scaffolding that tailors the learning process to the child’s current ability—in other words, teach. In addition to its obvious role in the cultural transmission of complex skills such as weaving (Greenfield, 1999), instruction functions very widely in human cultures in the service of different kinds of cultural transmission (Kruger & Tomasello, 1996).

Collaboration

This process involves two learners of approximately equal skill and cognitive capacity in relation to the problem at hand. Rather than one teaching the other, they co-construct a solution by learning interactively (Kruger, 1992, 1993;

Kruger & Tomasello, 1986). As with true instruction, collaboration requires two-way perspective taking, such that each learner can see the problem as the other sees it. (This is sometimes attributed to “theory of mind,” although that designation seems to imply something much more elaborate than perspective taking.)

Psychodynamic Processes (Emotional Enculturation)

Attachment

Attachment to a primary caregiver and then to other individuals, both human and nonhuman, provides the foundation for ongoing social interaction fundamental to social learning and ultimately to socialization. Social skills emerge and are practiced in this emotionally rich context, reinforced by emotional rewards and punishments. In human cultures, this process not only socializes the young but also forms a major part of enculturation.

Positive Identification

This emotional process organizes imitative tendencies by focusing them on one or more individuals to which the child feels similar, likes, and/or admires. This process is involved in the formation of gender-specific behavior in all cultures, as well as behavior specific to a clan, a class, or to the cultural group itself.

Fear of Strangers

Xenophobia, or fear of strangers, sets a limit very early in life on the outward reach of identification and imitation. It drives infants and children toward primary caregivers and makes within-family identification stronger.

Negative Identification

Xenophobia may (and does in most cultures) develop by middle childhood into prejudice against an outgroup. This may entail hatred, disgust, and/or fear, and these strong emotions form the basis of a desire to be different from the outgroup, thus reinforcing ingroup cultural identity.

Emotion Management

Because unsettling inner experiences, including anxiety, fear, grief, rage, hunger, lust, and fall-

ing in love, among others, are pervasive in life, human cultures provide rules and rituals that calm the anxieties associated with such experiences. This transforms a highly intense individual experience into a collective one, and it changes an experience that feels idiosyncratic and disturbing to one that is and has been shared by others.

Symbolic Processes (Cognitive Enculturation)

Cultural Construction of Perception

Because the brain routinely sets the sensitivity of sense organs, selecting and shaping input, the opportunity arises in human experience for culture to shape perception by shaping cognition. Thus the cultures whose languages make no phonemic distinction between *l* and *r* produce toddlers who never again attend to the distinction, although making it is a trivial matter for 2-year-olds in other cultures. Culture also shapes many other forms of perception (Sapir, 1994).

Cultural Schematization

Cultures do more than filter perception at the sense organs. They actively build schemas (models) to represent the complexities of the world and give structure to thought (Shore, 1996). Thus, in cultures such as those of highland New Guinea, goods and services flow toward one man who commands the respect of others, and who then can be (more or less) relied on to redistribute them (as well as other goods and services) in ways that are culturally appropriate. There is a strong tendency in these cultures to see all of economic and social life in terms of this model or schema.

Narrative Construction

The human propensity for creating narratives orders life in a temporal dimension much like that of the life course itself, with a beginning, a middle, and an end (Bruner, 2003; Bruner & Feldman, 1996). Stories can be true or invented, funny or sad, instructive or baffling, cynical or edifying, and end happily or tragically, but every one of them helps to order life events in a way that is meaningful and at least somewhat comprehensible. Just as the narrative of one's own life, accurate or not, gives it meaning and orders future events against its

background, so the narrative of a culture's history—suffering and the overcoming of it for the Jews, independence and pioneering for Americans—functions for a people.

Cultural Coherence

Cultures appear to have themes (usually more than one), and these may organize many schemas into a linked web of cognitive function (Durham, 1991; Shore, 1996). Warlike toughness may have been such a theme for the Plains Indians and the Yanomamo, cooperation for the Japanese, competition for Americans, and positive attitude for the Balinese. Although at best gross oversimplifications, they may make the large array of symbols and schemas in any culture cohere to some extent, and make them easier to learn.

IMPLICATIONS FOR CULTURAL PSYCHOLOGY

Postmodernist skepticism about human universals notwithstanding, research has progressed along many lines, including neo-Darwinian approaches to human culture (Barkow et al., 1992; Betzig, 1997), D. E. Brown's (1991) survey of universals (Brown, 1991), and Shore's (1996) attempt to place psychological anthropology on a foundation of recent cognitive science. As Shore notes, "A kind of cognitive romanticism . . . has begun to crystallize" (p. 35) in cultural anthropology, founded on the fallacy that "if cultural practices or beliefs are not fully determined or universally shared . . . then they must be arbitrary and thus infinitely variable" (p. 37). This extreme position, itself ironically an example of the human mind's universal dualizing tendency, has been espoused by Richard Schweder: "The mind, according to cultural psychology, is content-driven, domain specific, and constructively stimulus bound; and it cannot be extricated from the historically variable and cross-culturally diverse intentional worlds in which it plays a constitutive part" (as quoted by Shore, p. 36).

This strong version of the claim is clearly false; in large part, the mind can be so extricated, as shown by work of Darwin, Eibl-Eibesfeldt, Ekman, Tooby, Cosmides, and many others in evolutionary psychology, and by the work of Boas, Lévi-Strauss, D'Andrade, Shore, and other cultural anthropologists who accept in some form the reality of a universal

human cognitive apparatus. Even if cognition is inherently dialogic, that does not rule out important universal characteristics of the dialog shared among different cultures and even different social species. The weak version of the statement has always been embraced by anthropologists and now, thanks to cultural psychology, psychologists accept it as well. Except in extreme pathological instances, no human child can develop without culture, and so all human behavior, thought, and feeling is tinged or brushed or saturated with cultural color, and this color is different in different traditions. More importantly, much of the content of mental life is different, in the same sense that different languages have different content but for the most part serve similar functions and even share many fundamentals of structure. Finally, behavior is regulated by culture in myriad ways that allow us to feel protected and accepted, and to fend off the anxiety that would come with having an infinite range of choices every moment of every day.

Yet behavior too shows universal features that are far from trivial, and somehow almost all cultures direct behavior, thought, and feeling toward final common pathways of survival and reproduction. Some developmental psychologists have also run the risk of cognitive romanticism, claiming that Vygotskian cultural psychology should largely supplant the discoveries of Jean Piaget and others about universal processes in human mental function and its development (Bruner, 1999; Fernyhough, 1997; Rogoff, 1990; Rogoff, Baker-Sennett, Lacasa, & Goldsmith, 1995). That a limited number of mainly observational studies in this field could have so revolutionary an effect seems implausible, and, indeed, the claim is not sustained by the evidence, but it finds a comfortable place in the postmodernist rhetoric of recent and even current academia—a "hegemonic discourse" in its own right.

In fact, although learning to weave in a Mayan community in Highland Guatemala has been cited as support for Vygotskian models of mental development (Rogoff, 1990, Chapter 6), the same process in a village in Zinacantan, Mexico has been shown to support a Piagetian approach (Greenfield, 2005, Chapter 2). Not only are the developmental patterns compatible with Piagetian models but also the "Zinacantecs' implicit theory of development corresponds to Piagetian theory" (pp. 48–49). Teaching is important, of course, as are the

tools of instruction, but they do not take the place of maturation. Indeed, “the tools show us specific cultural expressions of universal stages of development while simultaneously showing us the Zinacantecs’ implicit conceptions of these stages. They reveal that a theory of cognitive development and a developmental theory of instruction are built into the culture” (p. 49). In other words, even culture-specific models of teaching and learning are constrained by universal facts of maturation.

Again, there is a weaker form of the claim that cannot be denied—enculturation is an important aspect of mental development—but the strong form, in which there are few or no universals of mental function and its development, is demonstrably false. But, of course, cultural psychology has an important subject matter even when its claims are not exaggerated: the real variation in psychological processes across cultures and the understanding of how culture affects cognitive function (Lehman, Chiu, & Schaller, 2004). Equally important, it has filled a gap left by the postmodernist rejection of scientific method in much of cultural anthropology. What relevance does evolution have for this important enterprise? I answer this question in four ways.

First, since psychological processes have evolved, the starting point for cultural psychology must be the cognitive apparatus brought forward from our higher primate background. These capabilities evolved under selective pressures, increasingly accessible to investigation, that explain much of human behavior and mental life. Cultural variation follows particular paths that begin with the hunter-gatherer baseline and diverge in ways that are sometimes predictable from neo-Darwinian principles. It may be that Japanese and other East Asian cultures have a corporate or collective bias compared with the individualistic bias in the United States (Markus & Kitayama, 1991; Triandis, 2001), although even this widely accepted generalization is open to challenge (Voronov & Singer, 2002). But an anthropologist might argue that this collective bias is present in all hunter-gatherers and most traditional societies in the anthropological record. So the question may be not “How do East Asian cultures bring about this distinctive cultural bias?” but “Why did the United States and a few other Western cultures abandon a pattern that had previously been a central part of the human adaptation?”

Second, psychological processes are instantiated in the brain, and any cognitive models, cultural or not, must come to terms with rapidly advancing knowledge of higher brain function. Quite soon, the brain will be the standard cognitive model. Plasticity is substantial, but it has both firm limits and favored pathways with which culture must come to terms as it influences the mind. Lévi-Strauss (1962, 1963) showed that so-called “primitive” cultures all tend to dichotomize the social world and to represent the respective halves with potent totems or symbols whose relationship to each other mirrors that of the social groups. Modern states, or collections of states, also fit this pattern, as in the confrontations of the Cold War or the war on terror, perceived by many as a conflict between Christianity and Islam. If this is a widespread or universal human mental tendency—Lévi-Strauss would have said that dualities are “good to think”—then it would be interesting to know why in terms of brain function, and it would be especially interesting to understand the cultural psychology—and the cultural psychobiology—of people (e.g., Norwegians or Tibetans) who seem to transcend this tendency better than do others.

Third, the study of cultural variation always reveals invariant properties of behavior and mind. Not only cross-cultural universals, of which there are many, but also cross-cultural biases—departures from a random distribution of variation—often reveal evolved properties of mind instantiated in the brain. In the realm of language, cross-cultural hierarchical regularities in color naming, phonetics, and grammar set firm limits on the observable variation (Berlin & Kay, 1969; J. H. Greenberg, 1975), and this is undoubtedly true of other dimensions of culture. For example, compared with the North, the Southeastern United States may have a “culture of honor” (Cohen et al., 1996; Nisbett, 1993), but so do inner-city gang members reacting to what they perceive as a disrespectful glance, and hunter-gatherers experiencing a presumed insult in the process of meat distribution. The question therefore is not “What is unique about Southern cultural psychology?” but “What do the many cultures of honor have in common psychologically that distinguishes them from those in which honor is less important?”

Finally—culture notwithstanding—the course of human development is first of all maturational, proceeding according to a plan set and

guided by the genes. This plan may provide opportunities for culture to be especially effective in shaping mind, and it would be useful to understand these opportunities and when they occur. For example, does the widespread tendency of traditional cultures (including Japan) to have infants sleep in the same bed, or at least in the same room, with their mothers provide some kind of psychological foundation for the collective bias of their cultures, or does the causal arrow go the other way? Does the American practice of letting a baby cry itself to sleep in its own room until it gets used to sleeping alone foster independence, or is it just a by-product of our culture of independence? Or both? At this point in the history of this science, whether we call it psychological anthropology or cultural psychology, we simply do not know.

CONCLUSION

Cultural psychology represents the realization by psychologists of something that psychological anthropologists have known and investigated for a century: Culture has profound influences on mind that go beyond habitual or customary behavior, and mind in turn may help explain the uniqueness of cultures. This is a welcome development, because these phenomena merit study, and anthropology does not have the resources to do justice to all of them, nor, in the wake of the postmodernist revolution (Greenfield, 2000), does it usually approach them with the kinds of quantitative methods psychologists use. However, there are many exceptions (D'Andrade, 1992, 2001; Heider, 1991; LeVine, 1999, 2002; LeVine et al., 1994). Better communication between the two groups might be of value, along with greater recognition by cultural psychologists of the history of their much older sister discipline. Also, cultural psychology has been slow to recognize the contributions of biological anthropology and evolutionary psychology. These approaches explain the baseline from which cultural divergences depart, as well as indicate some predictable ways those divergences are distributed. Behavior is adaptation, and culture aids or impedes adaptation in different ways for different human groups. In the future, neurobiological studies will help us to understand both the constancies and varieties of human minds as they develop in different cultures. It is

often said that nothing in biology makes sense except in the light of evolution. Little in behavior, mind, or culture makes much sense except in the same light.

PART II

THEORY AND METHODS

CHAPTER 5

Cultural–Historical Activity Theory

Integrating Phylogeny, Cultural History, and Ontogenesis in Cultural Psychology

MICHAEL COLE
GIYOO HATANO

This chapter presents an approach to cultural psychology that broadens the issue of culture and *ontogeny* to place the study of culture and human nature in a broad evolutionary and historical framework. We take as our theoretical starting point the position developed by L. S. Vygotsky and his colleagues that human psychological processes can be understood as the emergent outcome of four “genetic domains”—phylogeny, cultural history, ontogeny, and microgenesis (Vygotsky, 1977; Vygotsky & Luria, 1930/1993; Wertsch, 1985). Although the work of the early cultural–historical psychologists is in some respects out of date and can be faulted on various grounds, their emphasis on the constitutive role of culture in development and their broadly inclusive evolutionary framework provide an advantageous foundation upon which to build an integrative cultural psychology.

The expansion of cultural psychology in the direction proposed by early Russian cultural–historical psychologists is an important contemporary task for several reasons. Whereas

those who consider themselves cultural psychologists would not deny that human nature is heavily constrained by our species’ phylogenetic heritage, examination of the relationship between phylogeny and culture in ontogeny has, with some notable exceptions, been marginal to development of the field. (For examples of such exceptions see Greenfield, 2004, and Tomasello, 1999, whose work falls under the scope of our present concerns.)

For example, Shweder and his colleagues (1998) explicitly state that human beings are creatures with a long, common phylogenetic past that provides constraints on ontogenetic development. They also invoke ideas about the influence of experience on development that come directly from neuroscience. However, they do not explore how these phylogenetic factors are linked to human ontogeny, restricting themselves to pointing out that whatever these primeval, shared, characteristics are, they “only gain character, substance, definition and motivational force . . . when they are translated and transformed into, and through, the con-

crete actualities of some particular practice, activity setting, or way of life” (p. 871). In a similar manner, Rogoff (2003) also presupposes, but does not analyze, species-specific phylogenetic foundations of cognitive development, focusing instead on historical changes in cultural practices and shifting modes of participation within and between cultural practices during ontogeny as the cornerstone of her approach.

In light of contemporary evidence, we adopt a version of the early cultural–historical psychologists’ approach that can be briefly described as a “skeletal constraints plus cultural practices” view of cultural psychology. This perspective has won a number of adherents in recent years, among both psychologists who typically do not invoke culture as a constituent of development (e.g., Gelman & Kalish, 2006) and those who do (Shweder et al., 2006). This position makes contact with increasingly popular work in the fields of evolutionary developmental psychology and comparative developmental evolutionary psychology, which do focus on the relationship between phylogeny and ontogeny but unfortunately pay little attention to the role of cultural history (e.g., Bjorklund & Pellegrini, 2002; Parker, 2003). Our overall goal is to bring culture–history into the study of human ontogeny without abandoning a commitment to an evolutionary perspective.

BASIC IDEAS OF THE EARLY CULTURAL–HISTORICAL PSYCHOLOGISTS

The Russian cultural–historical school was founded on the assumption that the structural uniqueness and developmental course of human psychological processes emerge in the process of humanity’s culturally mediated, historically developing, practical activity (Leontiev, 1981; Luria, 1979; Vygotsky, 1987). Each term in this formulation plays a role in how we conceive of the interplay of phylogeny and cultural history in ontogeny.

Cultural Mediation

According to this approach, characteristically human psychological processes emerged in phylogeny simultaneously with a new form of behavior in which material objects are modified as a means of regulating their interactions with both the physical world and each other. It

was common at the time to refer to such mediational devices as *tools*, but we adopt the more inclusive concept, *artifact*, for reasons that will become clear later.

The basic idea of tool (artifact) mediation of human experience is clearly expressed by Alexander Luria (1928) in the first publication of the idea in English: “Man differs from animals in that he can make and use tools . . . [that] not only radically change his conditions of existence, they even react on him in that they effect a change in him and his psychic condition” (p. 493).

The consequence of tool creation/use for the basic structure of behavior is “that instead of applying directly its natural function to the solution of a particular task, the child *puts between that function and the task a certain auxiliary means . . .* by the medium of which the child manages to perform the task” (Luria, 1928, p. 495, italics in original).¹

This idea of tool mediation is, of course, not original to early Russian cultural–historical psychologists. It was also central to the ideas of many thinkers at the turn of the 20th century, who emphasized not only tool use but also the creation of tools that generated the idea of *homo faber* (see Cole, 1996, for an extended discussion).

Historical Development

Vygotsky and Luria (1930/1993) included both the history of the human species and historical change following the emergence of modern *Homo sapiens* in their approach to ontogeny. They asserted that the evolutionary, the historical, and the ontogenetic–genetic domains each has its own “turning point” in which *something new* is introduced into the process of development.

Their proposed turning point in phylogeny is the appearance of tool use in apes. The turning point in human history is the appearance of labor and symbolic mediation. The major turning point in ontogeny is the coming together of culture–history and phylogeny with the acquisition of language. The products of these fusions of different “streams of history” are the distinctly human, higher psychological functions.

The overall story concerning the processes of change went something like this: With the higher apes one reaches a point of anthropoid evolution in which tool use is observed (they

based the bulk of these ideas on Kohler’s work), bespeaking the phylogenetic development of practical intelligence. But there is more to the specifically human form of development than tool use.

In spite of the fact that the ape displays an ability to invent and use tools—the prerequisite for all human cultural development—the activity of labor, founded on this ability,² has still not even minimally developed in the ape. . . . This form of behavior [tool use] does not constitute the main form of adaptation for them. We cannot say that the ape adapts itself to its environment with the help of tools. (Vygotsky & Luria, 1930/1993, p. 74)

Tool use among humans has a different character:

The entire existence of an Australian aborigine depends upon her machines. Take the boomerang away from the aborigine, make him a farmer, then out of necessity he will have to completely change his life style, his habits, his entire style of thinking, his entire nature. (p. 74)

The crucial difference that distinguishes ape and human ability to use tools and human labor is the involvement of language and symbolic mediation, “tools for the mastery of behavior,” as well as nature. This combination produces a qualitatively new form of mediation, one in which tools and languages unite in the artifact. At this point “primitive man” emerges.

Vygotsky and Luria (1930/1993) note that the concept of “primitive man” is an abstraction, “the starting point of historical development” (p. 82). Yet, they argue, data about prehistoric humans (“the lowest rung of cultural development”) and people from different contemporary cultures can both provide evidence about the psychology of primitive man.

By their account, historical change from the original humans to modern adult humans occurs along two dimensions. First, there is an increasing use of cultural/mediated/higher functions in place of natural/unmediated/lower functions. Second, there is development in the complexity of the mediational means themselves.

In one of their favorite examples, Vygotsky and Luria (1930/1993) argued that in primitive cultures natural remembering, such as eidetic imagery, is dominant. Incidental memory con-

cerning participation in various events, what we might call “everyday memory,” also qualified as natural remembering, a process in which humans record the world but do not actively use their memories to transform it.

This sort of “natural” (to humans) form of everyday memory is built upon phylogenetically evolved, “elementary” psychological processes that are assumed to be universal across cultures and historical periods. “Cultural” memory develops through the elaboration of the “mediational means” by which memory is accomplished and the cultural practices that incorporate these new mediators. Tying a knot around one’s finger to control one’s memory from the outside and the Inca *quipu* provided clear examples of what Vygotsky and Luria (1930/1993) meant by the “cultural form of behavior.”

In short, according to this view, culture undergoes both quantitative change in terms of the number and variety of artifacts, and qualitative change in terms of the new forms of mediated behavior potentials that they embody. As a consequence, both culture and human thinking develop.

In summary, culture, according to this perspective, can be understood as the entire pool of artifacts (including language, norms, customs, tools, values) accumulated by the social group in the course of its historical experience. It is the species-specific *medium* of human development. The capacity to develop within this medium and to arrange for its reproduction in succeeding generations is *the* distinctive characteristic of our species.

Practical Activity

The third basic premise of the cultural–historical approach, adopted from Hegel by way of Marx, is that the analysis of human psychological functions must be grounded in everyday activities. A. N. Leontiev (1981) asserted the primacy of everyday activities with respect to cultural–historical psychology in the following vivid terms:

. . . human psychology is concerned with the activity of concrete individuals, which takes place either in a collective—that is, jointly with other people—or in a situation in which the subject deals directly with the surrounding world of objects—for example, at the potter’s wheel or the writer’s desk. . . . With all its varied forms, the hu-

man individual's activity is a system in the system of social relations. It does not exist without these relations. The specific form in which it exists is determined by the forms and means of material and mental social interaction. (p. 11)

Additional principles of the cultural-historical approach to cultural psychology follow from the three already mentioned.

First, because phylogeny, culture-history, and ontogeny are all processes that occur over time and for which change is the central phenomenon to be explained, a developmental approach is required. It is for this reason that Vygotsky often invoked the idea that "to understand behavior we must understand the history of behavior" (Vygotsky & Luria, 1993, p. 79).

Second, this perspective gives a special importance to the *social origins* of human thought processes. As Vygotsky (1929) argued, all means of cultural behavior (*artifacts* in our terminology) are social in their essence: "Social relations or relations among people genetically underlie all higher functions and their relationships" (Vygotsky, 1981, p. 163). This view of social origins arises because of the special role of adults as bearers of the cultural resources of the social group. It does *not* imply a passive child; recall from Luria's earlier statement that incorporating tools (cultural artifacts) into ongoing efforts to master one's environment is the essential marker of the "cultural form of behavior." From this perspective, the biologically maturing child and the socially organized, culturally mediated, social environment "co-construct" development.

A MODERN PERSPECTIVE ON PHYLOGENY AND DEVELOPMENT: HOMIZATION AND PRIMATOLOGY

In deciding to take the phylogenetic past of *H. sapiens* as a starting point for cultural psychology, two errors need to be avoided. First, as Wertsch (1985) pointed out, Vygotsky and his followers, in keeping with their contemporaries in the West (e.g., Kroeber, 1917), adopted a "critical point" theory of phylogeny-culture relations. A critical point theory assumes that at some moment in the distant past, culture arose as a "sudden, all-or-none type of occurrence in the phylogeny of the primates" (Geertz, 1973, pp. 62-63). There is, however, a

good deal of evidence to support Geertz's famous assertion of the *coevolution* of phylogeny and cultural history in the development from the early common ancestor of *H. sapiens* and its nonhuman primate "cousins." Because the human brain developed over millennia during which culture became an ever-more-essential part of human life, it seems necessary to take seriously Geertz's colorful assertion that

man's nervous system does not merely enable him to acquire culture, it positively demands that he do so if it is going to function at all. Rather than culture acting only to supplement, develop, and extend organically based capacities logically and genetically prior to it, it would seem to be ingredient to those capacities themselves. A cultureless human being would probably turn out to be not an intrinsically talented, though unfulfilled ape, but a wholly mindless and consequently unworkable monstrosity. (p. 68)

Contemporary paleological evidence indicates that culture is not an "add on" to a primal, biological human nature. Culture is a biological prerequisite to the normal functioning of the human brain (Plotkin, 2001).

A second problem with the early Russian cultural psychologists' treatment of phylogeny with respect to ontogeny was that it was only minimally developed (Wertsch, 1985). As indicated earlier, their basic idea was that phylogenetic ("natural") contributions to ontogeny are reflected in elementary, unmediated forms of behavior manifested in various psychological realms, including memory, attention, numeracy, and language. For example, with respect to concept formation, a topic of special concern in this chapter, they assumed that the phylogenetic contribution to ontogenetic change was restricted to general cognitive capacities that might change during ontogeny owing to maturation but that the development of systematic category systems depend upon participation in formal schooling, which itself evolved as a cultural institution in connection with the advent of writing. Current evidence, however, indicates that various cognitive capacities once thought to arise entirely from general learning mechanisms and maturation are present at birth, or at least well before the appearance of grammatical language and formal schooling. So a re-examination of the culture and phylogeny relationship with respect to fundamental processes of conceptual development is required

to avoid immediate dismissal by contemporary psychologists.

Our treatment of phylogeny, culture, and ontogenetic development is divided into three sections. The first discusses nonhuman primates' cognition and culture from a comparative cognitive science perspective. This discussion is closely related to what is called "phylogenetic development," but instead of examining primates' biological evolution based on archeological evidence, we exploit information from currently living species of nonhuman primates, especially chimpanzees, as our evolutionary neighbors. As will be seen, the reconstructed picture of phylogenesis using such evidence indicates that culture plays a minor, though significant, role in behavioral development and change among nonhuman primates.

The second section covers the process of hominization. It is generally agreed that human beings and chimpanzees/bonobos shared a common ancestor some 6 million years ago (Noble & Davidson, 1996). The successors to the common ancestor that lead to *H. sapiens sapiens* (some 20 species of which have subsequently disappeared) underwent massive changes not only in the brain and in physical morphology of the body (bipedalism; the structure of the arms, hands, fingers, vocal tract, etc.) but also in physical ecology, cognitive capacities, and the accumulation of the products of the past in the form of human culture. By contrast, there is no evidence that the anatomy, body size, physical morphology, behavior, cognitive abilities, and modes of life have changed markedly over the past several million years among chimpanzees or bonobos.

The third section covers the period of history following the "great leap forward," when human cultural capacities were clearly present. Change during this period has been particularly rapid; cultural–historical–social change is much faster than biological evolution, because our experiences can be accumulated and revised in the form of increasingly elaborated artifacts. In turn, human intellectual achievements are unique, because humans accumulate their experiences in the form of culture, so that offspring can access and incorporate them through language or other mediational means.

Taken together, the discussion in this section provides the essential context within which to consider human ontogeny and its relationship to human culture in evolutionary context, the topic for the last section.

Cognition and Culture among Nonhuman Primates

In the middle of the 20th century, Darwin's views to the contrary, Anglo-American scholars who considered culture a significant contributor to human development adopted the idea of "human exceptionalism," the belief that the human species is distinguishable by its cognitive capacities, which in turn owe their special powers to the involvement of culture in their operation. Despite challenging cognitive abilities shown by Kohler's apes and parallel experiments in Russia documenting apes' problem-solving skills, researchers have maintained that, in many crucial respects, human beings are not only quantitatively but also qualitatively different than other species in both their cognitive abilities and their use of culture as a medium of human life (these views are summarized in Cole, 1996). This view was not universal. For example, in Japan, where wild monkeys live, both professionals and laypeople regard them as human-like, though with several notable differences (e.g., the hairy body, a tail, slightly less intelligence).

The antiexceptionalism (continuity) side of this controversy, Darwinian saltation of cognitive capacity or cultural characteristics (producing a change in degree not kind), was revolutionized by such scientific milestones as DNA comparisons between humans and chimpanzees (Marks, 2002) and the ethnographic/ecological observations of communities of chimpanzees pioneered by Jane Goodall (1968). Such achievements made it more manageable to think of bonobos and chimpanzees as genetically and psychologically very similar to humans. Matt Ridley (2003) summed up the shifting conceptions of chimpanzee mental, social, and cultural capacities when he referred to Goodall's descriptions of chimpanzee behavior in the wild as "simian soap operas." Goodall's chimps deceived each other; "cheated" on each other, and even killed each other. They also used leaves and sticks to fish for ants, and their offspring seemed to learn from seeing them do this.

We first examine current evidence concerning tool use and cognitive abilities, consider evidence for the presence of culture among nonhuman primates. Then we turn to the question of culture–cognition relations in these species and the questions those relations pose for scholars interested in culture–cognition relations in human ontogeny.

Acquisition and Use of Tools

At least from the time of Kohler's classic studies of problem solving, a great deal of attention has focused on chimpanzee tool use and tool creation. McGrew's (1998) summary regarding tools clearly indicates the nature of current claims for chimpanzee tool use and toolmaking capabilities:

Each chimpanzee population has its own customary tool kit, made mostly of vegetation, that functions in subsistence, defense, self-maintenance, and social relations. . . . Many have tools sets, in which two or more different tools are used as composites to solve a problem. . . . The same raw material serves multiple functions: A leaf may be a drinking vessel, napkin, fishing probe, grooming stimulator, courtship signaler, or medication. . . . Conversely, a fishing probe may be made of bark, stem, twig, vine, or the midrib of a leaf. An archeologist would have no difficulty classifying the cross-cultural data in typological terms, based on artifacts alone; for example, only the far western subspecies . . . uses stone hammers and anvils to crack nuts. . . . Given this ethnographic record, it is difficult to differentiate, based on material culture, living chimpanzees from earliest *Homo* . . . or even from the simplest living human foragers. (pp. 317–318)

In at least one case it has been claimed that chimpanzees carry different tools with them to accomplish different goals (Boesch & Boesch, 1984). The chimpanzees in question encountered two kinds of nuts in their foraging, one with hard shells, the other with softer shells. For the harder nuts, they transported harder, heavier hammers (mostly stones) from their home base. They seemed to remember the location of stones and to choose the stones so as to keep the transport distance minimal.

Boesch and Boesch (1984) concluded that these chimpanzees possess a representation of Euclidian space that allows them to measure and remember distances; to compare several such distances so as to choose the stone with the shortest distance to a goal tree; to locate a new stone location with reference to different trees; and to change their reference point to measure the distance to each tree from any stone location. In a study with the bonobo Kanzi, raised in captivity, Savage-Rumbaugh and her colleagues obtained a similar result using lexigrams for location (Menzel, Savage-Rumbaugh, & Menzel, 2002).

Some tool use is reported also among monkeys. For example, Japanese macaques can be

trained to use tools skillfully, though they seldom do so in their natural environment. The monkeys, using a rake, can pull closer food that is placed beyond their reach after 2 weeks or so of training (Ishibashi, Hihara, & Irik, 2000). Interestingly, in these trained monkeys, “bimodal” neurons in the intraparietal cortex respond to visual stimuli not only near the hand but also surrounding the tool, suggesting that the tool becomes literally an extension of the body part. The monkeys can also be trained to use two tools successively, that is, to use first a nearby short rake to pull closer a long rake, then to pull closer food that can be reached only by the long rake. Moreover, they can learn to monitor the movement of their hand and tool on a video screen (Iriki, Tanaka, Obayashi, & Iwamura, 2001). The authors claim that though higher-order cognitive abilities such as tool use do not emerge spontaneously, this capacity exists and begins to manifest itself when there is external pressure to exploit it.

Culture among Monkeys and Apes

Belief in a narrow, quantitative gap between human and nonhuman primate cognition is paralleled by belief in a narrow gap with respect to culture (Wrangham, McGrew, de Waal, & Heltne, 1994). However, in making such claims, one must be mindful of the fact that the researchers adopt what might be called a “minimalist” definition of their object of study by focusing on culture as behavioral traditions spread or maintained by nongenetic means through processes of social learning. This kind of definition is useful because it does not presuppose characteristics that are themselves arguably specifically human (e.g., religious beliefs, aesthetic values, social institutions, etc.); hence, the analyst can remain agnostic with respect to culture–cognition relationships. It allows examination of the extent to which cognitive characteristics claimed to be necessary for acquisition of human culture are present in displays of nonhuman primate behavioral traditions (cultures) such as deliberate teaching or toolmaking and use. And it leaves open the question of how similar the cultures of humans and apes might be.

The textbook example of a tradition for which we know the origin and have data on its spread comes from sweet potato washing by Japanese macaque monkeys on Koshima Island. In 1953 a juvenile female monkey was observed washing a muddy sweet potato in a

stream. This behavior first spread to peers and then to older kin. Ten years later, it was observed among more than 50% of the population and 30 years later, by 71%. A few years later the same monkey invented a form of “wheat sluicing” in which wheat that had been mixed with sand was cast upon water, so that the floating bits of wheat could be easily sorted from the sinking sand. Within 30 years, 93% of the group engaged in this behavior. It is not clear whether this shared behavioral tradition was based on monkeys’ observational learning or imitation in the strict sense, or on the availability of environmental cues, including other members’ behaviors that attract their attention (Matsuzawa, 2003).

Such cultural traditions do not remain entirely static and need not bear any discernable relation to subsistence activities. A group of monkeys living in the far north adopted the tradition of bathing in warm springs in winter; initially the mothers left their offspring on the edge of the pools, but the young monkeys began to swim under water. Several groups of macaques routinely handle small stones in a variety of ways (rolling, rubbing, piling) that are not related to any discernable adaptive function. These observations blunt attempts to find restrictions of the observed cultural behaviors to subsistence constraints.

Chimpanzees have provided the most extensive evidence on nonhuman culture based not only on specially provisioned populations, such as the Koshima macaques, but also on several dozen wild populations and long-term studies in zoos and laboratories. The behavioral traditions involved have included ways of using probes for termites and ants, nut cracking by using sticks and stones in various ways, hunting strategies, nest building, and styles of grooming behavior (McGrew, 1998; Matsuzawa, 2001; Whitten, 2000; Wrangham et al., 1994). (Interestingly, in light of their importance in discussions of both primate language and cognition, bonobos in the wild appear to display no evidence of tool use. This species difference should serve to block any simple equation between tool use and either cognitive development or the existence of cultural traditions.)

Among chimpanzees, some tools may be left over and used again by other members of a group. In a sense, leftover tools constitute culture as a set of socially inherited artifacts. In fact, Hirata and Morimura (2000) found that leftover tools serve as environmental cues enhancing chimps’ observational learning of

honey fishing (an experimental simulation of ant/termite fishing found in the wild). Naive chimpanzees often observed their experienced partners after their own failed first attempts and also used the leftover tools of the experienced ones. Hirata and Celli (2003) further suggested that infant chimpanzees in captivity acquire honey fishing behaviors earlier than recorded in the wild not only by repeatedly observing the behaviors of experienced mothers but also by using selectively the tools often used by mothers.

In summary, this evidence indicates that there must be some evolutionary continuity between humans and other apes and monkeys in potential competencies. However, for the potentialities to be actualized, “a human-like social-cognitive environment,” or even human intensive teaching, appears necessary (Tomasello, 1994).

Culture and Hominization

A few relatively uncontroversial “facts” serve as anchors for more accounts of hominid evolution prior to the advent of modern human beings. The best available evidence is found with respect to morphological changes and to changes in material artifacts. More speculative is the evidence concerning the evolution of language and cognition.

Brain Size and Other Morphological Changes

There is a marked increase in the size of the brain in the sequence of species leading to *H. sapiens sapiens*. The most frequent way of calculating this increase is to represent brain size in relation to overall body size, which is referred to as an encephalization quotient (EQ; Falk & Gibson, 2001). The EQ of modern humans is almost three times that of the chimpanzee and other great apes. More interestingly, this growth appears to have been especially pronounced in the frontal and prefrontal cortices, hippocampus, and cerebellum, all heavily implicated in cognitive changes both in phylogeny and ontogeny. Of special interest has been the appearance, derived from endocasts (moldings of the inside of skulls) of increased brain volume in Broca’s area that appears with the advent of *Homo erectus*, because of the relationship of Broca’s area to language in normally developing modern humans.

Also widely studied have been morphological changes in other parts of the body that are

associated with species changes following divergence from the common ancestor. Such changes include bipedalism and various changes in anatomy, with significance for hominization such as changes in the hand implicated in fine motor control (especially the opposable thumb), the pelvic region (which is crucial to the timing of birth and the length of infancy), and the vocal apparatus necessary for rapid a fluent speech (see Lewin & Foley, 2004, for a summary).

Bipedalism is often considered to be the first step toward hominization, because whereas the EQ of members of *Australopithecus* was about the same as that of present-day chimpanzees, there is clear evidence that some of them were bipedal walkers. Bipedalism required radical morphological changes that might have endangered early ancestors' lives in the trees, where they were relatively safe. Moreover, bipedalism was *not* absolutely necessary in the wood-savanna mosaic region where they initially lived. Its direct advantage was that bipedalism in the upright posture was more economical in the use of energy for long-distance locomotion, thus enabling bipedal creatures to get food from a relatively wide geographical area. Bipedalism changed selection pressure, because different morphological characteristics became adaptive.

Changes in Material Artifacts

Data relevant to the cultural sphere, particularly the evidence of changes in material artifacts, are perhaps the second most reliable source of evidence concerning cognition-culture relations (Foley & Lahr, 2003). *Australopithecus*, or even the common ancestor, can be assumed to have used stone tools because chimpanzees do so, but they may not have made clearly identifiable artifacts. The first, crude tools are usually said to appear with *Homo habilis*, the earliest *Homo*. These tools, called Oldowan artifacts, were made of stone according to most interpreters, and appear to have been made by shattering small rocks to make sharp-edged implements (choppers) and additional tools, such as knives made by chipping off flakes from the remaining stone core. Although they were not very sophisticated, producing them seems beyond bonobo's capability (Toth, Schick, Savage-Rumbaugh, Sevcik, & Rumbaugh, 1993). The tools were used, it is believed, mainly for cutting dead animals into

small pieces, because, unlike *Australopithecus*, which was mostly herbivorous, *H. habilis* was a scavenger who ate the animal protein needed to grow and maintain its enlarged brain.

H. erectus is generally believed to provide evidence of a quantum increase in size and the complexity of the cultural tool kit. According to this line of interpreting the fossil record, tools now included hand axes with two cutting edges, which required a much more complex manufacturing process.

With respect to the way of living, which is inferred from the tools and the uses to which they were presumably put (e.g., cutting up large animals for meat, and skins used as clothing), as well as evidence of group size and patterns of food consumption, *H. erectus* appears to have been a "critical turning point." For the first time there is evidence of creatures who lived in relatively permanent base camps, had stone tools that clearly differed from any claimed for other species, and ventured out to hunt and gather. *H. erectus* revealed a reduced sex difference in size, implying changes in male-female relationships—for example, a male may have helped a female who had to take care of an infant for an extended period of time because it was born in an immature state. *H. erectus* had molar teeth reduced in size, which suggests that the species had to masticate less owing to the use of fire for cooking. It was also *H. erectus* that ventured out of Africa and made its appearance in Asia and Europe.

It should be noted that, initially, change in the hominid tool kit was exceedingly slow, lasting perhaps a million years. The rate of change, the variety, and the complexity of tools increased in the course of human evolution, although the timing of changes is disputed (Foley & Lahr, 2003; Lewin & Foley, 2004). This fact has potentially important implications. First, cumulative cultural evolution, or the "ratchet effect" (Tomasello, 1999) is not always clearly observed; culture as a set of shared artifacts may have been inherited by the following generations almost unchanged. Second, insofar as culture is stable and enduring, it often induces selection pressure for particular types of competence (e.g., for designing and manufacturing an axe). Generally speaking, when there are genetically transmitted variations among group members in a number of properties, which ones are adaptive (i.e., advantageous for having many offspring) is determined by not only the natural but also the sociocultural environment.

Evolution of Language and Cognition

When we get to *H. erectus*, some scholars argue that language was one constituent of a pattern of increased cognitive and cultural complexity (Bickerton, 1990; Deacon, 1997; Dunbar, 2004). Others argue that language came later, or with the advent of *H. sapiens sapiens*, owing to the development of a specialized vocal tract that could produce rapid speech (Lieberman, 1984). We believe that these conflicting views can be reconciled by assuming a few stages in the evolution of language. For example, protolanguage (Jackendoff, 1994), which mainly relies on two-word combinations, may have appeared early and functioned well, because even pidgin is quite useful for communication within a small and familiar group. In contrast, syntactically more sophisticated language may have appeared fairly late, as more precise and detailed information had to be communicated in a larger group. Whether early or late in hominization, symbolic language is agreed to be essential to the emergence of modern humans.

Suggestions for important cognitive changes that may have accompanied language include increased ability to coordinate motor and spatial processing (Stout, Toth, Schick, Stout, & Hutchins, 2000; Wynn, 1989), increased ability to cooperate with others over extended periods of time to produce standardized products (Foley & Lahr, 2003), and increased ability to imitate the behavior of others (Donald, 1991, 2000; for discussion of Donald's views, pro and con, see Renfrew & Scarre, 1998).

An intriguing puzzle in the story of hominization is the apparent “great cognitive leap forward” that seems to have occurred approximately 45,000 years ago. V. S. Ramachandran (2000) succinctly describes this discontinuous change in the following way:

The hominid brain grew at an accelerating pace until it reached its present size of 1500 cc about 200,000 years ago. Yet uniquely human abilities such as the invention of highly sophisticated “standardized” multi-part tools, tailored clothes, art, religious belief and perhaps even language are thought to have emerged quite rapidly around 40,000 years ago—a sudden explosion of human mental abilities and culture that is sometimes called the “big bang.” If the brain reached its full human potential—or at least size—200,000 years ago why did it remain idle for 150,000 years? (p. 4)

Whereas some posit a genetic mutation to account for these changes (Berlim, Mattevi, Belmonte-de-Abreu, & Crow, 2003), as Ramachandran points out, it appears most likely that rapid environmental changes brought together heretofore isolated hominid groups, creating the conditions for the emergence of those cultural innovations that make us uniquely human. This position has been bolstered by evidence of a great many species whose remains have been found in Africa, bespeaking the presence of various elements of the “human revolution” (new technologies, long-distance trading, systematic use of pigment for art and decoration) tens of thousands of years earlier than previously thought but never fully developed in one place (McBrearty & Brooks, 2000). By this latter account, the “human revolution” was simply “human evolution” in which many isolated changes in different species came together with the changes in climate and population that brought disparate peoples together 40,000 years ago in Europe.

Still another interpretation is in terms of increased fluidity among domain-specific knowledge systems (Mithen, 1996). Mithen claims that whereas Neanderthal's stone toolmaking, social skills, and natural history knowledge were as advanced as those of modern humans, they were unable to integrate the knowledge located within each of these domains. In contrast, modern humans could produce, for example, artistic cave drawings and tools well suited to their target use, by integrating needed pieces of information across domains.

We refer briefly to mirror neurons in this context. Mirror neurons are activated both when an animal observes and when it executes a specific action. Such neurons have been observed in the premotor area of monkeys (Rizzolatti & Craighero, 2004) and are assumed to exist in the corresponding area of human and other great apes' brains. The neurons seem to serve as the basis of the understanding and imitation of others' actions (Brass & Heyes, 2005; Rizzolatti, Fadiga, Fogassi, & Gallese, 2002). Some researchers (e.g., Ramachandran, 2000) speculate that mirror neurons provided primates with the foundation for the development of the theory of mind, language, and culture.

It is certainly premature to attribute any definite role to mirror neurons in the formation of these characteristically human competencies.

We would suggest a more conservative view than the authors cited in the preceding paragraph, because although mirror neurons may facilitate, they cannot be the sufficient condition for a social-cognitive development such as imitation. Monkeys, and even chimpanzees in the wild, seldom imitate. Having mirror neurons is at best a genetic potential, the realization of which needs the right ecological conditions. Mirror neurons are probably not the necessary condition either, because there can be other routes for the acquisition of socio-cognitive skills (e.g., “emotional reactivity”; Hare & Tomasello, 2005).

A Tentative Conclusion

If we seek to rise above the myriad disagreements among those who attempt to synthesize analyses and interpretations regarding the processes of hominization, the most important conclusion for our purposes is that the relations between biological, cultural, and cognitive change are reciprocal. The “virtuous circle” that the evidence most strongly supports is that changes in anatomy (increased relative brain volume) is linked to a change in diet, in particular, greater intake of protein from the killing and ingestion of animals. The ability to kill and eat animals was in turn linked to concomitant anatomical changes (the ability to run long distances that evolved following the evolution of the ability to walk upright, which also freed the hands and was accompanied by greater dexterity of the fingers). These biological changes were both cause and result of increased sophistication of the cultural tool kit, including the control of fire (a clearly cultural practice, but one whose origins are disputed across a million year margin). The development of a richer diet, and the way of life associated with it, enabled the growth of new cognitive capacities, which further enriched the cultural tool, which in turn further supported growth of the brain, and so on. As Henry Plotkin (2001) emphasized, human evolution and cultural evolution are two-way streets of causal interactions.

CULTURAL HISTORY

Although there are innumerable differing explanations for the causes of the transition to *H. sapiens sapiens* (a genetic change; a change in climate enabling increased interactivity among

groups of *H. sapiens*, creating a critical mass of cultural isolates; some combination of the above; etc.), there is reasonable agreement that the following key features indicating the presence of genetically modern *H. sapiens* were observable between 40,000 and 50,000 years ago, the “high Paleolithic” period of paleontology:

1. Semeiosis, or the act of creating signs that stand for objects and number.
2. Production of second-order tools to create a variety of new tools, such as points, awls, needles, pins, and spear throwers.
3. An ability to visualize the complex action of tools or simple machines.
4. Complex spatial–structural organization of living sites.
5. Long-distance transport of raw materials such as stones and shells over tens or even hundreds of kilometers.
6. Rapid expansion of human populations into territories previously occupied by earlier, developed forms of humans and rapid replacement of the indigenous populations.
7. Further expansion into territories not previously inhabited by humans.
8. An increase in population densities to levels comparable to those of hunting and gathering societies of historical times (Cheyne, n.d.).

Here, it appears, is the beginning of modern humans, the “cavemen” and “hunter-gatherers” of anthropological, paleontological, and historical lore.

A number of sources present a roughly agreed-upon story of changes following the emergence of biologically modern humans over the next 35,000 to 40,000 years (cf. Diamond, 1997; Donald, 1991; Gellner, 1988). Some of the hunter-gatherers who inhabited parts of the earth and lived in small bands went on to engage in sedentary agriculture. Among some agriculturalists there emerged in some places aggregations of people into city-states and a marked increase in sociocultural complexity (Feinman, 2000). Among others, older ways of life continued in very much the same way for millennia.

A defining characteristic of the Paleolithic period was the appearance of external systems of symbolic, representational cave art, statuary, and perhaps elementary counting devices (Donald, 2001). According to Damerow (1998), it seems most reasonable to consider the many millennia between the beginning of

the Paleolithic period and the Neolithic period around 8,000 B.C. (when people began to domesticate plants and animals, and live in permanent villages) as a historical equivalent of the transition from sensorimotor to preoperational thinking. If, as McGrew (1987) argues, such societies approximate the level encountered in small, face-to-face societies during the European age of exploration, it provides evidence in favor of the assumption that the cognitive processes of such peoples are best characterized as preoperational (Hallpike, 1979).

According to both Damerow (1998) and Donald (1991, 2001), the urban revolution coinciding with the smelting of copper, and then bronze, and the elaboration of tools, weapons, and agricultural techniques, marks the transition from preoperational to operational thinking in human history. Two important lessons for contemporary studies of culture and human ontogeny are emphasized by this literature. First, when concrete operational thinking begins to make an appearance, it is tightly bound to particular domains of culturally organized activity. Second, the causal relations between the development of culture and the historical development of cognition were reciprocal. Like Plotkin (2001), quoted earlier, who was referring to the process of hominization, Donald (2000) is emphatic in his conclusion that the brain and culture “have evolved so closely that the form of each is greatly constrained by the other” (p. 25). Moreover, with the advent of literacy especially, “culture actually configures the complex symbolic systems needed to support it by engineering the functional capture of the brain for epigenesis” (p. 23).

However intriguing, the difficulty with using prehistoric and even historical materials that have survived only in images and stone artifacts is that we have too little information about their contexts of use to make refined inferences about culture and cognitive development in ontogeny. Moreover, the notion that people in small, face-to-face, nonliterate societies had the cognitive capabilities of 3- to 5-year-old children living in industrialized societies has been rejected on both theoretical and empirical grounds (cf. Laboratory of Comparative Human Cognition, 1983). For these reasons, studies enabled by rapid cultural–historical change in most parts of the world over the past several decades are particularly valuable. Conditions of rapid cultural–historical change make it easier to tease apart

relations between cultural–historical and ontogenetic change, because there are coexisting generations close to each other in age that engaged in markedly different culturally organized activities but were phylogenetically speaking, contemporaries.

Cross-Sectional Cultural–Historical Comparisons

Perhaps the most well-known study to focus on the relation of rapid cultural–historical change to cognitive change was carried out by Alexander Luria (1976) in the early 1930s. Luria studied a cohort of people under conditions of rapid change in remote parts of the Kyrgyzstan and Uzbekistan.

The historical occasion, the collectivization of agricultural labor under state control, brought with it changes, such as formal schooling, modern labor, and exposure to bureaucratic state agencies, during what can fairly be described as a revolutionary period in that part of the world. Luria concluded that the new modes of life deeply affected the dominant modes of thought, such that the “premodern” group was restricted to a form of “graphical/functional” reasoning based on common experience, while modernization brought with it access to scientific concepts that replaced graphical/functional thinking.

Luria’s conclusions are open to at least two criticisms. First, according to the basic methodology underlying his theory, Luria’s data should have come from either direct observation of people engaged in identifiable indigenous activities (or schools and collective farms) or experimental models of those activities. Instead, he used the results from psychological tasks originating in studies of developmental changes, or the effects of brain damage, among Europeans. The interview situation itself was an alien form of activity to the traditional pastoralists who served as subjects in Luria’s experiments, so that their responses may have reflected as much the alien nature of the modes of discourse as the influence of their own cultural experience employed in indigenous activities. Second, the failure to gather data from the theoretical site of change, the activities themselves, made it difficult to grasp the change processes at work and made it appear that the changes from concrete–graphic to theoretical thinking were of a general nature.

Subsequent research replicating Luria’s results in different parts of the world confirmed his basic empirical observations but cast doubt

on his conclusions of general cognitive change associated with schooling or involvement in modern economic enterprises. Tulviste (1979), Scribner (1977) and Scribner and Cole (1981), among others, found that a few years of schooling increased dramatically the tendency of people to respond to syllogistic reasoning problems “theoretically,” that is, in terms of the logic of the problem as presented, whereas those with little or no schooling responded in terms of their empirical knowledge about the contents of the problems presented. But these same authors presented evidence of theoretical reasoning among nonschooled people, whereas others have shown that even highly educated people are likely to depend upon their empirical knowledge of the contents of the problem presented in many cases (D’Andrade, 1989). The result has been a convergence on the conclusion that cultural–historical variations in cognition (i.e., verbal syllogistic reasoning) arise from, and are closely related to, the introduction of new forms of activity (Tulviste, 1999). New forms of reasoning become general only insofar as the activities giving rise to them are general in the society in question.

Research by King Beach (1995) in an area of Nepal undergoing rapid historical change appears to overcome some of the uncertainties of Luria’s approach and its replications by including indigenous activities discovered through ethnographic observation in psychological problem-solving tasks that were themselves modeled on the activities observed. Beach studied changing forms of arithmetic calculations in a Nepalese village that underwent rapid socioeconomic and cultural change in the 1960s and 1970s. As roads from India moved closer to the village, schooling was introduced for the first time and continued to expand over ensuing decades. Shops that exchanged merchandise for money appeared during the same period and rapidly increased in number.

At the time Beach initiated this research in the late 1980s, two coexisting generations of Nepalese men had experienced different relations between their experience of traditional farming and new cultural institutions such as shopkeeping and schooling. All groups shared some experience with subsistence agriculture and the need to buy and sell in the shops using traditional nonmetric units to measure a given length of cloth, then calculate their price in terms of meters and centimeters, to which the monetary price was linked. However, whereas

the traditional system relied on using the length from the elbow to the tip of the middle finger, the newly introduced system involved use of a ruler and the metric system.

Some senior high school students were apprenticed to shopkeepers in the village, whereas some shopkeepers who had never had the opportunity to attend school were enrolled in an adult literacy/numeracy class. Farmers who had never attended school or worked in a shop also completed a shopkeeping apprenticeship or were enrolled in the adult education class. The transitions between education and work activities induced as a part of Beach’s (1995) study simulated larger-scale changes taking place in rural Nepalese society.

Some of the mathematical problems posed by Beach (1995) to track changes in arithmetic during the shop apprenticeship involved purchases requiring translation and calculation between the two measurement systems. Arithmetic problems presented to those enrolled in the adult education class were the kind typically encountered in school mathematics classes.

Traditionally, shopkeepers used indigenous arithmetic forms that bear little surface relationship to either metric measurement (arm lengths vs. a metric measuring stick) or to the methods of calculating amounts and prices (the use of objects and other artifacts, as well as traditional decomposition strategies, vs. the use of paper and pencil to write equations and calculate with column algorithms). Those students becoming shopkeepers continued to use the written form they had learned in school after they entered the shops, even though reliable traditional methods long in use were prevalent there. Over time and with much pressure from the shopkeeper and customers, the students adapted their written form to the calculation strategies used by the shopkeepers. Those who began as shopkeepers and were studying in the adult education class initially used their arms and traditional measurement objects to carry out their calculations but eventually adopted a flexible approach, sometimes using traditional measurement units and calculation strategies, and at other times doing written calculations adapted to the problem.

From interviews with the participants, Beach (1995) was able to determine that students who were becoming shopkeepers viewed themselves as engaged in two activities that initially contradicted each other—school learning and shopkeeping. The status of schooling and of

“being educated” made it difficult for them give up the written form of calculation, though the speed and adaptability of the shopkeepers’ calculations eventually induced them to adapt their written form to the shopkeepers’ calculation strategies. In this way their status as formally educated adults was retained, marked by their use of writing, but they could use the written form to do the calculations they needed to do as shopkeepers more quickly and accurately. Even though they were in an evening school, the shopkeepers always thought of themselves as engaged in shopkeeping activities (their own shopkeeping activities) and shifted over to the school-based system only when they saw that it facilitated their ongoing work as shopkeepers. By virtue of both the tasks he presented and the way he presented them, Beach verified the links between cultural–historical and ontogenetic change that depended on both the history of relations between the activities and the individuals’ developmental history when they began to participate in those activities. Beach’s results point to a process of culturally inflected ontogenesis that is much more variable and more content–artifact–activity-specific than Luria’s results would suggest.

Longitudinal Studies of Cultural–Historical Change

Despite differences in methods, the research by Beach (1995) and Luria (1976) involved people with different amounts of exposure to new cultural practices. The studies are, in this sense, cross-sectional developmental studies.³ In the longitudinal studies briefly sketched in this section the same developmentalist returned after many years to the same cultural group, so that it is possible to document the course of cognitive development under changed sociocultural conditions at two disparate historical times.

Historical Change and Cognitive Change in Zinacantan

In the late 1960s, Greenfield and Childs (1977) went to a Mayan community in the state of Chiapas, Mexico, where they began to study the cognitive and social consequences of learning to weave. Their work included experimental tests of categorizing ability by both boys and girls, careful descriptions of the weaving process of women and young girls being apprenticed into weaving, and analysis of the

products produced. In the 1990s they returned to the same village and conducted parallel observations of parents (former child subjects) inducting their children into weaving and the products of this work (Greenfield, 1999; Greenfield, Maynard, & Childs, 2000).

In recent written comparisons of the relation among cultural change, modes of weaving, and modes of weaving instruction, Greenfield has emphasized the interconnectedness of historical change in economic activity, exposure to new products and practices resulting from contact with people representing the modern sector of Mexican society, changed socialization practices (in particular, modes of socializing girls into weaving), and changed cognitive processes involving the mental representation of the patterns in woven cloth (Greenfield, 2002, 2004; Greenfield et al., 2000). These changes are viewed as interconnected.

The analysis begins with historical changes in general modes of living. In contrast with the late 1960s, by the mid-1990s this Mayan community had shifted from an economy based primarily on subsistence agriculture and relative seclusion from the modern state to one based more heavily on involvement in the money economy, trade, and much more frequent interaction with people and trade from outside the village and the local region.

The instructional mode characterizing the mother–child weaving sessions in 1970 emphasized a long process of socialization involving many roles preparatory to weaving itself. When children first began to weave, mothers hovered close by and guided children with their own hands and bodies, using little verbal instruction. The entire system appeared to focus on maintenance of tradition that Greenfield and her colleagues (2000) characterized as “interdependent cultural learning.”⁴ In the 1990s, mothers who were more involved in the modern economy (e.g., by weaving products for sale) instructed their children verbally from a distance, sometimes using older siblings to take over instruction, and the children learned by a process that Greenfield and her colleagues characterize as “independent cultural learning,” characterized by a good deal more trial and error and self correction of errors.

The variety of products also changed. In the late 1960s, the variety of products was limited, reflecting a very small set of “right ways to weave cloth.” By the 1990s there was no longer a small set of simple, “correct” patterns, but an

efflorescence of patterns, indicating the increased respect paid to individual innovation that comes with a trial-and-error approach to learning. This proliferation in turn depended upon, and contributed to, changes in weaving practices.

Accompanying these historical changes were changes in the way children represented weaving patterns in an experimental task by inserting sticks of varying width and color into a rack to reproduce model patterns from woven models. Instead of using, for example, three white sticks to represent a broad band of white cloth, they were more likely to use a single broad white stick in the later historical period, and those who attended school were more likely to be able to create novel patterns. Importantly these historical changes were accompanied by an unchanging pattern of representational development related to age: Older children in both historical periods were more able than younger children to represent more complex visual patterns, a fact that Greenfield et al. (2000) interpret as an indication of universal developmental processes accompanying culturally contingent ones.

Based on her decades-long involvement with a Mayan community in the Yucatan, Suzanne Gaskins (1999, 2000, 2003) notes the same kinds of economic changes observed by Greenfield and her associates (2000) but provides a different, although compatible, explanation of the causal factors involved. Gaskins focuses on how the changing economic circumstances change maternal work patterns, suggesting that reduced time spent on traditional chores (e.g., hauling water because there is running water, or having a longer day because of electricity) and in the commercial sector outside the home shifts the division of labor inside the house in a variety of ways that reduce direct parental involvement with children's socialization in general, not just with respect to specific practices such as weaving.

Differences in interpretation of underlying process notwithstanding, the Greenfield et al. (2000) multigenerational study brings a whole new range of data to bear on the question of the mechanisms of cultural change and accumulation, suggesting a strong link between cultural change resulting from the interaction of cultures and the development of new means of teaching and learning that accompanies the shift to more intensively commercially mediated forms of life.

The Cultural Evolution of Arithmetic in New Guinea

A second "longitudinal cultural-historical" study was begun in the late 1970s by Geoffrey Saxe and his colleagues, who conducted a number of developmental studies among the Oksapmin from a remote area in the highlands of central New Guinea (Saxe, 1982, 1994). The number system used by the Oksapmin became the subject of longitudinal cultural-historical comparisons.

Traditionally, the Oksapmin use a 27-digit counting system based upon body parts, beginning with the pinky of the right hand and ending at the pinky of the left hand. When Saxe first arrived, he found the traditional number system in wide use, but that people who had traveled to earn money at nearby tea and copra plantations were likely to bring back a taste for not only some of the goods they encountered there but also money (a heretofore unknown phenomenon), which could be exchanged for those desirable consumer goods. Moreover, the outside world had penetrated Oksapmin life sufficiently for there to be schools whose teachers taught in an English-related pidgin language, in which children learned base-10 arithmetic and the standard calculation procedures.

More than two decades later, Saxe and Esmonde (2005) returned to the Oksapmin. As one means for studying population variations associated with various schooling experience or the use of money (which was now much more prevalent in the area because of increased trade in agricultural products and the introduction of mining in not-too-distant areas), Saxe and Esmonde traced the cultural history of a single lexical item, *fu*, demonstrating that it underwent a number of changes during the period between 1978 and 2001. When Saxe first went to New Guinea, traditional Oksapmin, who had not yet learned pidgin, used *fu* to refer to the completion of counting a set of objects, as in "1 . . . 27, done." During the ensuing 20 years, the English system of 20 shillings to the pound, which was relatively new to the Oksapmin when Saxe was first there, was replaced by a national Papua New Guinea (PNG) base-10 system, in which 10 units that functioned like shillings summed to 1 PNG denomination called a *kuan*. People used the same term to refer to a 2-*kuan* note as that used to refer to a pound. In both cases, the number 20 is of exceptional importance. Saxe and Esmonde found that the number 20, which is at

the left elbow, became a privileged site in the body counting system, and at the same time, *fu* took on the new function of referring to completion of a count of shillings/2 PNG *kuan*.

As a result of treating developmental change over a cultural–historical epoch as a focus of interest, Saxe and Esmonde (2005) were faced with the possibility that the changing meanings of *fu* were not the result of conscious human effort to create a more powerful arithmetic. Rather, this “cognitive development” emerged as a by-product of the mixture of ways Oksapmin use their language and their bodies to represent number through their participation in the ever-changing, and ever-more-commercialized social and economic exchange practices in which people engaged.

Although examples of research that combine the study of cultural–historical and ontogenetic change remain scarce, each example justifies the general assumption that cultural–historical change is an important constituent of ontogenetic change, justifying the basic assumption that the traditional dialectic between phylogeny and ontogeny must be expanded to include cultural change as an essential ingredient to the process of human development.

CULTURE AND BIOLOGY IN ONTOGENY: CORE DOMAINS AND CULTURAL PRACTICES

Contemporary accounts of cognitive development point to the need to combine two active areas of research if we are to provide a synthetic account that does justice to both the phylogenetic and the cultural–historical constraints from which the ontogeny of cognitive development emerges. The first area emphasizes phylogenetic contributions to cognitive development that manifest themselves particularly in infancy and young childhood, and, according to some, at birth. The second area focuses on cultural practices characteristic of the social group into which the child is born.

Phylogenetic Contributions

Early-appearing phylogenetic contributions to ontogeny are of two general kinds. The first are psychological processes organized in terms of “core,” or “privileged” domains. Such processes display characteristic domain boundaries and task specificity. Each represents a particular class of entities for a particular set of

purposes (Spelke, 2000). Widely accepted candidates for such core domains supporting naive, domain-specific theories include naive physics, naive psychology (theory of mind), and naive biology (Wellman & Gelman, 1998).

In addition to such domain-specific constraints, researchers have also identified powerful general learning mechanisms. Even infants are able to identify sequential dependencies in the speech stream (Saffran, Aslin, & Newport, 1996) or in the mechanical movement that occurs when one object collides with another (Baillargeon, 1994). Moreover, humans early on are conceptual learners. They are able (1) to build concepts coherent within a larger system (Mandler, 2004); (2) to understand a set of antecedent–consequent pairs in terms of unobservable, mediating forces (Tomasello, 1999); and (3) to “bootstrap” (i.e., create a new system of representation that is more powerful than those present; Carey, 2004).

These general learning mechanisms are also products of evolution, but not in response to task-specific adaptation. They are heavily dependent on enlarged frontal and prefrontal cortices that may have evolved through uniquely human ways of living, such as posing and solving complex interpersonal and social problems, learning and using culturally inherited artifacts, adapting the natural environment to their needs, and so on (Quartz & Sejnowski, 2002).

Cultural Contributions

Whatever the initial constraints that characterize knowledge acquisition in core domains, such knowledge is woefully inadequate to normal adult human functioning; they are skeletal, not structurally complete (Gelman, 2000; Hatano & Inagaki, 2002). Consequently, ontogenetic development of the human mind requires repeated participation in culturally organized practices. Cultural practices are a bridge between phylogeny and ontogeny. On the one hand, the cultural history of a child’s social group provides the kinds of practices that are available, their relative frequency, and their accessibility as proximal environments for development. On the other hand, developing individuals increasingly have at least limited freedom to choose the practices in which they engage and to change the features of these practices through their participation. Even when participants have no choice but to participate in a cultural practice, and have no desire

to improve their skills, repeated participation enhances the cognitive, social, and physical skills needed to perform well in these practices.

Practices vary greatly both within and between social groups. In some cases people acquire skills to perform competently only in a specific practice, whereas in other cases they acquire a rich and well-structured body of knowledge and associated skills as well. Among these knowledge-rich domains, they may further acquire conceptual knowledge that helps them to modify known procedures flexibly, to invent new procedures, and to employ their knowledge in a wide variety of practices. Gaining cognitive competence may require years of experience in solving problems in the domain and often takes the form of “deliberate practice” requiring sustained concentration (Ericsson, Krampe, & Tesch-Romer, 1993); alternatively, it may be achieved readily and promptly, based on a small number of experiences (Wellman, 2003).

The amount of time and effort required to gain expertise in a given cultural practice or with respect to a particular cognitive domain (depending upon whether one is dealing with a core domain and its skeletal principles or a domain of social practice for which no obvious skeletal principles appear) is currently uncertain. It seems plausible that when dealing with core domains, acquisition to a level broadly characteristic of the adult population should be relatively rapid and effortless, whereas acquisition of cultural practices that bear no clear relation to any known core domain would be slower, more effortful, and require specialized arrangements. So, for example, natural languages appear to be acquired rapidly, without any explicit instruction (in fact, young language learners may acquire a natural language even when doing so is discouraged, as in the case of deaf children placed in oralist schools run by hearing people; Padden & Humphries, 1988). By contrast, learning to read English, or to fly an airplane, is rarely accomplished without explicit instruction and a great deal of practice. Human beings evolved to speak natural languages. Tens of thousands of years were required for them to invent written languages or to construct and fly airplanes, and to this day, such knowledge is not universal.

As Keil (2003, p. 369) commented, “Most people seem to live in worlds of the artificial,” which immediately poses a problem. Although people may be able to make inferences about

function from observing someone using an artifact, and inferences about their intentions, there appear to be no straightforward, domain-specific “core principles” that will help them draw proper inferences about the categories of artifacts involved and the functions they fulfill outside of core domains. Gelman and Lucariello (2002) made this point using examples such as learning to play chess, history, algebra, economics, literature, and so on. They argued that learning in the absence of support from core domains presents considerable challenges

because there is no domain-relevant skeletal structure to start the learning ball rolling. The relevant mental structures must be acquired *de novo*, which means that learners acquire domain-relevant structures as well as a coherent knowledge base of domain-relevant knowledge about the content of the domain. . . . It is far from easy to assemble truly new conceptual structures and it usually takes a very long time. Something resembling formal instructions is often required and still this is not effective unless there is extended practice and effort on the part of the learner. (p. 399)

Within the framework presented here, deliberate instruction is a subset of the general category of historically evolved cultural practices. Consequently, the constraints that arise from the patterned forms of interaction that structure a great variety of cultural activities may serve to enable concept formation in non-core domains. Unfortunately, to date, relatively little developmental research has been conducted with these issues in mind, beyond the social practices associated with various forms of formal schooling, although some relevant research can be gleaned from what has come to be known as the study of “everyday cognition” (Rogoff & Lave, 1984; Schliemann, Carraher, & Ceci, 1997). The work of Greenfield (2004; Greenfield et al., 2000) on changes in classification associated with apprenticeship in weaving provides one such example. This work implicates a variety of general learning mechanisms, including the ability to detect sequential dependencies, imitation, and intent observation (Rogoff, Paradise, Arauz, Correa-Chavez, & Angelillo, 2003).

Knowledge acquisition in non-core domains also requires particular forms of social organization that are likely, as Gelman and Lucariello (2002) suggest, to require more elaborate forms of sociocultural organization than in

cases where skeletal principles provide a “leg up” on the acquisition process. We return to this issue below. Because knowledge and skills, whether or not anchored in core domains, are acquired in particular cultural practices, their cognitive consequences tend to be specific to that practice and the cognitive domain(s) with which it is associated. However, at least some domain-general development can also be expected as the consequence of experience with different practices. Such broad experience is primarily due to the fact that some activities occur across so many different settings and/or some artifacts are used so widely that they can have cognitive consequences well beyond particular domains. Narratives, orthography, and measurement are just a few examples of such activities and associated artifacts. Such general learning is also aided by cultural models that indicate the relevance of one activity to another, thereby stimulating generalization across settings/activities (Laboratory of Comparative Human Cognition, 1983). To the extent that there is coherence in culture, it is because of the commonality of contents, forms of the activities, ethnotheories of the linkages between different activities, and generally useful artifacts that characterize the lifeworlds of the people involved.

Because human life involves a broad range of cultural practices, each of which may involve a mixture of privileged and nonprivileged domains, and a concomitant mixture of domain-specific and general learning mechanisms, it is not possible to specify a single path of ontogenetic cognitive development independent of the domains and cultural practices in which individuals engage. We can, however, determine how processes of learning and development differ in cases where the domains and cultural practices are relatively well known to get an idea of the range of processes at work. We begin with a case where privileged domains and cultural practices are closely associated and proceed to a case where the cultural practice, while involving a core domain, involves rich knowledge and complex skills well beyond those specified by the core domain in question.

Complementarity of Domain-Specific Constraints and Cultural Practices

As we have noted, knowledge systems in privileged domains occur under constraints that direct developing individuals’ attention and cod-

ing, simultaneously restricting the range of their interpretations of observed connections, allowing them to be acquired to at least a modest level of complexity early and without difficulty. Such cognitive developments can be expected to be relatively universal across cultures. But this does not mean that cultural mediation plays no role in their development.

The emergence of naive biology provides a good example for purposes of exposition, because the presence innate, domain-specific constraints in relation to naive theories and later development has been the subject of considerable research (Inagaki & Hatano, 2002). Our fundamental assumption is threefold. First, we assume that innate constraints for the acquisition of a naive theory of biology are skeletal principles that allowed our ancestors to survive (e.g., avoid dangers from other animals, find food). We do not assume that humans are born with propositional forms of biological knowledge, because constraints as dispositions can effectively mitigate learnability problems, and because it is hard to believe that specific biological knowledge can be genetically transmitted or neurally prewired. Moreover, because the process of evolution is very slow, possessing specific pieces of innate knowledge may be detrimental when ecological environments change.

Second, though we use the term “innate,” we might more precisely say “present at birth or acquired very early.” It is almost impossible using behavioral studies to show convincingly that a given domain-specific tendency or bias is innate in the sense of being manifested at birth. We can reasonably assume that such a bias is innate, however, when it emerges very early in infancy, without any seemingly responsible experience, when is observed universally both across and within cultures, or when its absence can be attributed to the deficit of a particular part of the brain.

Third, although we use the expression “domain-specific,” we are not sure whether a particular core domain constraint is applicable to just one naive theory. We do not know yet how infants and young children divide their knowledge into domains. So by “domain-specific,” we mean only to claim that the constraint is highly relevant to the acquisition of a theory in the particular domain.

These basic assumptions imply, first of all, that humans can readily acquire knowledge in core domains, although they are not born with

these bodies of knowledge. In other words, innate constraints greatly enhance learning but do not make learning unnecessary. A number of domain-specific and general learning mechanisms may be involved.

For example, humans tend to pay attention to those aspects of animals that serve to distinguish them from nonanimals (e.g., they differentiate those that move spontaneously from those that do not). There is evidence indicating that even infants make the animate-inanimate distinction on this basis (Mandler, 2004). Humans also have tendencies to attend to certain features, states, and behaviors of animals: They classify animals based on their size and ferocity (Atran, 1998); they pay attention to whether animals are active, hungry, and so on; and animals' eating and excretion are often eye-catching—all of which seem adaptive for humans in the “wild environment” (Toda, 2000).

Plants share with animals the fact that they are alive. Human attention may also be directed to plants in order to find food. It would be important for hunters-gathers to be able to use subtle cues by which they could distinguish plants and their products (that are potentially edible) from nonliving natural objects (e.g., pieces of clay or rocks). It is also important for farmers to pay attention to the states of their plants, such as whether they are healthy, growing vigorously, producing fruits and seeds, or catching some disease, and so on.

Humans also display preferences for antecedent-consequent pairings or causal attribution, in other words, a set of constraints that serves to eliminate in advance a large number of logically possible interpretations or hypotheses about events. Whereas some of these constraints work in highly specific situations, others work in a variety of settings. Many animals, including humans, display a tendency to search among a variety of foods for one that has made them ill, so that only a single trial (assuming they survive), even with a considerable delay between ingestion and painful symptoms, is sufficient to learn to avoid foods that have made them sick (Revusky & Garcia, 1970).

Nonetheless, participation in cultural practices is central to the development of rich knowledge about plants and animals. This kind of developmental process is illustrated by Inagaki (1990), who arranged for 5-year-old Japanese children to raise goldfish at home, whereas as a comparison group had no such experience. The goldfish raisers soon displayed

far richer knowledge about the development of fish than their counterparts who had not raised fish. They could even generalize what they had learned about fish to frogs when asked, for example, “Can you keep the frog in its bowl forever?” They answered, “No, we can't, because goldfish grow bigger. My goldfish were small before and now they are big” (quoted in Inagaki & Hatano, 2002, p. 144).

Additional evidence in favor of cultural involvement in the development of biological knowledge comes from the work of Atran and his colleagues on the growth of biological classifications (Medin, Ross, Atran, Burnett, & Blok, 2002; Ross, Medin, Coley, & Atran, 2003). Working among Yucatecan farmers, Native American rural dwellers, and a variety of urbanized people, these researchers found that factors such as density of experience and local ecological significance contribute to the development of biological understanding beyond early childhood.

Another piece of evidence is that whereas Israeli children tend to be underinclusive in their categorization of living species, separating out plants, Japanese children tend to be overinclusive. The difference, it is proposed, reflects the presence of different narratives in particular cultures: Israeli culture contains a well-known Biblical passage in which plants are described as created to provide food for animals, birds, and insects, whereas Japanese culture contains a number of stories that encourage the perception of many inanimate objects as possessing life (Hatano et al., 1993; Stavy & Wax, 1989).

Development in Cultural Practices That Amplify Core Domain Abilities

As noted earlier, whereas knowledge in privileged domains may be present in an elementary form early in life, the development of high levels of knowledge and skill, what is ordinarily termed *expertise*, requires repeated participation in culturally organized practices. The domain of number provides interesting examples of the way that cultural factors enter into the process of development beyond their rudimentary forms.

Studies of numerical reasoning in early childhood indicate that it builds upon these early starting conditions in an orderly fashion. Thus, for example, Zur and Gelman (2004) report that when 3-year-olds who had not attended

preschool viewed the addition or subtraction of N objects from a known number were asked to predict the answer, then check their predictions, they provided reasonable cardinal values as predictions and accurate counting procedures. Such rapid learning in the absence of explicit instruction, they argue, supports the idea that there are “skeletal mental structures that expedite the assimilation and use of domain-relevant knowledge” (p. 135). Such data, despite uncertainties about mechanism, support the argument for number reasoning as a core domain, and, hence, a human universal.

Evidence from number development in other cultures, however, leaves little doubt that Hatano and Inagaki (2005) are correct in arguing that because innately specified knowledge is still skeletal, it is essential to study the ways cultural experience interacts with phylogenetic constraints to produce adult forms of numerical reasoning. Many societies in the world appear to have at most a few count words on the order of “one, two, many” (Gordon, 2004; Pica, Lemer, Izard, & Dehaene, 2004). For example, Gordon (2004) has recently reported that Pirahã adults living in a remote area of the Amazon jungle have a restricted number vocabulary of this type, and that cultural practices involving number are virtually nonexistent. They display elementary arithmetic abilities for very small arrays of objects, but their performance quickly deteriorates with larger numbers. Saxe (1982) reports similar findings for the Oksapmin of New Guinea, who rarely used their base-27 number system as part of traditional systems of exchange of farm surplus.

Expertise in abacus operation nicely illustrates how domain-specific cognitive skills develop when a society creates artifacts and cultural practices to support more complex cognitive achievements (Hatano, 1997). An abacus, an external memory and computational device, can register a number as a configuration of beads, and one can find the answer to a given calculation problem, in principle, by manipulating them. It is no longer used widely in day-to-day commercial activity in Japan, but the abacus still constitutes a significant aspect of Japanese culture because it survives as a special artifact, and skilled use of it is valued in circles of enthusiasts. It survives also as an instructional tool: Quite a number of children go to private after-school instruction for abacus training, and a few of these become enthusi-

asts. To put it differently, abacus operation is embedded in two kinds of practices, educational and hobby.

People can learn how to operate a (real) abacus in an elementary but serviceable manner in a few hours when they participate in deliberate instruction. Advanced training is geared almost entirely to accelerating the speed of the operations involved. Cultural values respecting the speed of calculation are shared among abacus operators.

As a result of extensive training, abacus operation tends to be gradually interiorized to such a degree that most abacus masters can calculate accurately, and even faster without a physical abacus present, than with the instrument itself. During mental calculation, it appears that they can represent an intermediate, resultant number on their “mental abacus,” in the form of a mental image of the configuration of beads onto which (mentally) they enter, or from which they remove, the next input number. In other words, abacus experts can solve calculation problems by mentally manipulating the mental representation of abacus beads. The interiorization of the operation is an important mechanism for accelerating the speed of calculation, because the mental operation is not constrained by the speed of muscle movement. Thus, expert abacus operators use the real abacus only when they deal with very large numbers that cannot be represented on their mental abacus.

Some abacus operators calculate extraordinarily rapidly (Hatano, 1997). When mixed addition and subtraction problems (e.g., $957 + 709,143 + 386 + 2,095 - 810 - 91,748 + 105 \dots$) are presented in print, experts manipulate 5–10 digits per second. Remarkable speed is also observed for multiplication and division. Experts give, for example, an answer for 3×3 or 4×2 digit multiplication within 5 seconds. When they use a real abacus, they are basically error-free. Their mental calculation is not entirely free from errors, but their accuracy is quite respectable.

As might be expected, abacus experts’ calculation is highly automatic. Experienced abacus operators can converse during calculation, even without the instrument. The conversation cannot be very demanding—usually, just a short and simple factual or preferential question–answer exchange is required. However, this feat is remarkable considering the fact that we generally ask people around us to be

quiet when we calculate, especially when we do so without paper and pencil.

Expertise in mental abacus operation also induces changes at the neuronal level. For example, using event-related functional magnetic resonance imaging (fMRI), Tanaka, Michimata, Kaminaga, Honda, and Sadato (2002) showed that whereas ordinary people retain series of digits in verbal working memory (revealed as increased activation in the corresponding cortical areas, including Broca's area), mental abacus experts hold them in visuospatial working memory, showing activations in the bilateral superior frontal sulci and the superior parietal lobe. Hanakawa, Honda, Okada, Fukuyama, and Shibasaki (2003) demonstrated, using fMRI, that the posterior superior parietal cortex is significantly more activated while mental additions are performed among mental abacus experts than among nonlearners of the abacus.

The case of gaining expertise in abacus operation (both material and mental) exemplifies the sociocultural nature of expertise (Hatano, 1997). Pupils who attend abacus lessons are usually first sent there by their parents, while the children are in elementary school. The parents often believe that the exercise will foster children's diligence and punctiliousness, as well as enhance their calculation and estimation ability. Young pupils are motivated to learn abacus skills to get parental praise, especially by passing an exam for increasing qualification ranks. Like many other out-of-school domains of learning in Japan, abacus learning has an elaborate qualification system and frequent exams. It nicely fits with, or even is encouraged by, the fact that Japanese culture emphasizes effort rather than ability (Sato, Namiki, Ando, & Hatano, 2004).

The students' motivation changes when they join an abacus club at school or become a representative of the abacus school, in other words, when the operation is embedded in a different kind of practice. Abacus enthusiasts compete in matches and tournaments, just as tennis or chess players do. Also like these players, abacus club members not only engage in exercise at least a few hours every day but also seek knowledge of how to improve their skills. Their learning is strongly supported by the immediate social context of the club and the larger community of abacus operators. Formal and informal relationships with an instructor and peers organize their way of life, and sanc-

tions from other players regulate their daily activities. Moreover, they may participate in the community of abacus operators by taking an administrative role in players' organizations, as well as by serving as an examiner or a judge at matches and tournaments. They participate more and more fully by assuming more and more significant responsibilities in the community.

Abacus operators are also socialized in terms of their values, for example, regarding the importance of abacus skills and their status in general education, as well as their respect for the speed of calculation mentioned earlier. In fact, the community of abacus educators and players constitutes a strong pressure group in the world of education in Japan. In this sense, gaining expertise is far from purely cognitive. It is a social process (Lave & Wenger, 1991) that involves changes in values and identities (Goodnow, 1990). The experts' values and identities are undoubtedly forms of "culture in mind," acquired through internalization. They serve as the source of motivation for experts to excel in the target domain.

Interactive Sociocultural Constraints

As clearly shown by these examples, we can reasonably assume that most, if not all, forms of cognitive development, whether or not their content is focused on (or implicates) core domains, are induced through participation in culturally organized practices. Participants in these practices are motivated to perform well because the process and product are interesting and/or significant, and positively sanctioned by the culture. Moreover, inclusion in such practices is facilitated owing to interactive sociocultural constraints that make it possible for novices/newcomers to participate in roles that are appropriate to their level of expertise, so that what should be done for the activity as a whole can be done by flexible arrangements of the division of labor.

This kind of sociocultural arrangement is often referred to as a "zone of proximal development" or "legitimate peripheral participation," each of which indexes interactional dynamics that provide sociocultural constraints on, and supports for, development (Lave & Wenger, 1991; Vygotsky, 1978). These constraints are realized when other people who have extensive prior experience and shared physical, symbolic, and social tools help novices/newcomers/develop-

oping individuals acquire knowledge and skills through continuous interpersonal interaction.

For example, imitation plays an important role in the initial phase of learning to operate an abacus, and more mature members of the abacus learner community, in addition to serving as role models, give hints and suggestions for improving the skills. The construction of an abacus itself adds useful constraints, often specifying what should be done next—for instance, something different has to be done when there is not a sufficient number of beads left to enter a new addend.

This kind of process is illustrated in a different way when children raise an animal at home (Inagaki, 1990). In one likely scenario, children acquire knowledge from their parents or older siblings who already know how to raise the animal of interest. The children are likely to learn the procedures involved promptly, because their observation and choice of procedures are directed by joint attention with, or by imitation of, their more mature partners. In addition, active engagement in raising animals may lead children to acquire conceptual knowledge or a mental model of the animals being raised, often helped by guided comprehension activity engaged in for the sake of the animals. The children tend to be more competent when they engage in a joint activity than in a solitary activity, and they construct and elaborate on relevant pieces of knowledge more promptly (see also Rogoff, 2003).

The artifacts (including the routines) used in raising animals also serve to direct children's attention and narrow the range of procedures and interpretations they consider. For example, the manual for raising goldfish and other pets may include some information that is understandable to the children. A fish tank or a cage may suggest what kind of care the animal needs. Special food may be available, so that the procedure for feeding the animals can readily be standardized. Although the enabling constraints offered by such artifacts are primarily for the practical purpose of successfully raising the animals, they tend to enhance the acquisition of knowledge as well.

To generalize, when interacting with other people, our cognition and learning are constrained in the following ways (Hatano & Inagaki, 2005; Tomasello, Call, & Hare, 1993): What we observe is not randomly selected out of an almost infinite range of information but is directed by joint attention; what

we try to do is not to choose randomly a chosen chain of responses from our repertoire but is often triggered by imitation; and how we interpret a set of observations is influenced by guided comprehension activity. Tools also serve to direct our attention and narrow the range of procedures and interpretations we consider. For example, a machine helps us realize how to use it properly, because it does not respond when our actions are incorrect or are performed in the wrong order. In short, sociocultural constraints enable us not only to be competent but also to acquire knowledge and skills readily.

Even young children acquire knowledge and skills in a uniquely human way, in other words, through participating in practices. Their learning is helped by interactive sociocultural constraints, the operation of which is based on children's ability to represent other people's mental representations mentally (Tomasello et al., 1993).

Domain Characteristics and Cultural Support for Innovation

The case of expertise in mental abacus operation is informative, because it shows without a doubt that a set of cognitive skills is a form of culture in mind, derived from skills using an artifact that initially exists outside the mind. It is also clear that cognitive growth in a domain is associated with the development of corresponding values, identity, and status in the community of practitioners. However, the domain of abacus operation does not represent many other knowledge-rich domains that require learners to solve new problems using the knowledge in an adaptive and creative fashion.

First, abacus experts do not learn much about entities in the world or theoretical notions. It is true that they have constructed a mental model of a physical abacus, but it represents only highly restricted aspects of the physical device by which they may be able to find solutions to a limited range of problems very quickly. Second, abacus experts are characterized by their efficiency in applying acquired procedures and/or running an impoverished mental model in rather fixed ways. Therefore, their expertise is basically reproductive in nature; that is, they do not enrich the culture of the entire community of abacus operators.

In contrast, experts in domains such as science and everyday problem solving (e.g., cook-

ing, arts, and interactive games like chess) often acquire, in addition to skills for using solution procedures or routines, conceptual knowledge in the form of cultural–mental models of both concrete and abstract entities, as well cultural–mental scripts (event schemas) that can be used to run mental simulations, much as the mental abacus can simulate actions with a material abacus (Collins & Gentner, 1982). Relying on a mental model of the target object, experts in these domains can understand the meaning of each step of solution routines, modify the routines flexibly, and predict what will occur in novel situations.

Experts in cooking, for example, when deciding what to do next, are no longer heavily dependent on other people's knowledge or knowledge given in an externalized, symbolic form (e.g., a printed recipe or the advice of an experienced cook; Hatano & Inagaki, 2005). They are less dependent on devices and materials, though the physical environment, such as a frying pan filled with oil, may serve as a reminder. The expert cook can often tell which steps have to be performed in the prescribed order and which do not, add different ingredients from those called for in the standard recipe, choose different cooking tools when needed, and still make essentially the same or equally delicious dish. Their conceptual knowledge is both an individual construction and a form of culture in mind, because it reflects the knowledge shared by experienced members participating in the practice that has been manifested in prior joint activity. Moreover, problem solving in these knowledge-rich domains also involves considerable exploration and search, in other words, processes to generate a variety of new ideas and to evaluate how well these ideas work. Therefore, it is not rare that individuals, after gaining expertise, contribute to the cultural change. Expert cooks may invent new dishes by mentally combining a variety of materials and modes of cooking. The invented dishes may be incorporated into the culture of cooking, if their taste attracts a number of members constituting the community of cooks.

To put it differently, in these domains, culture can remediate itself by allowing (or even encouraging) its members to deviate from tradition. Innovations can be realized with resources that are available in the culture but not extensively used by a majority of its members, as in the case of an ethnic or local food's gaining popularity. Alternatively, the new knowledge can be produced through noncon-

ventional individual construction based on the database the culture provides. In either case, the cultural sanction enhances or inhibits innovation, either directly or indirectly. As we have seen, as the variety of products increased to attract tourists who visit Zinacantan, the process of production and learning changed toward the increased respect paid to individual innovation (Greenfield, 2004). Early childhood education practices in China have changed dramatically in the past 20 years toward emphasizing creativity because of the national goal of raising entrepreneurs who can be successful in the world economy (Hsueh, Tobin, & Karasawa, 2004).

CONCLUSION

In recent years one encounters an increasing number of programmatic claims that human ontogeny is the emergent outcome of phylogenetic, cultural–historical, and moment-by-moment (microgenetic) processes (Engeström, 1987; Rosa, Vega, & Gomila, 2004; Wertsch & Tulviste, 1992; Vygotsky, 1978). But since the early work of Vygotsky and his students (e.g., Vygotsky & Luria, 1930/1993), there has been little systematic effort to flesh out this programmatic statement, in terms of existing empirical data, from the many disciplines involved. At the same time, Vygotsky's name is often associated with cultural psychology (e.g., Nisbett, Peng, Choi, & Norenzayan, 2001; Shweder et al., 1998). Our major goal in writing this chapter has been to assess the viability of an approach to cultural psychology that retains the early commitments of cultural–historical psychology to an integrated evolutionary, historical, developmental approach to the problem of culture in mind.

The one part of the cultural–historical program on which we have not focused in this chapter has been the study of microgenetic processes. Microgenesis is present, of course, in all of the studies that use ethnographic and experimental methods to make their claims about culture and human psychological processes, but owing to lack of space, we have kept our discussion of culture and ontogeny at a fairly general level. Readers are invited to consult research such as Beach's (1995) study of arithmetic in shops, Coles' work (1996) on early reading instruction, or Greenfield's (2004) study of Zinacantecan weaving practices, for a more appropriate level of detail, as well as formulations

by the mainstream developmentalists who have incorporated sociocultural factors into their research (e.g., Granott & Parziale, 2002).

Within the limits imposed by the existing data, limits of space, and our own intellects, we believe we have found ample reason to adopt the original programmatic claim when considering the topic of culture and cognitive development.

First, it is clear that rudimentary forms of culture-as-behavioral-tradition can be found in chimpanzees, whose brains are approximately the size of the presumed common ancestor shared by humans and chimpanzee. At the same time, evidence on language acquisition and problem solving among nonhuman primates suggests that under some conditions (often, as a result of living with and being trained by humans), chimpanzee and bonobo symbolic and cognitive capacities reach a threshold approximated by the capacities of 24- to 36-month-old children. Consequently, strong claims for human uniqueness based on the presence of culture or tool use appear untenable, although culture appears to play a notably more restricted role in chimpanzee cognitive and social life (Latour, 1996).

Evidence from studies of hominization indicates that the differentiation between human and nonhuman primates, which began approximately 6 million years ago, has resulted from a dialectical interaction that takes place in the line leading to *H. sapiens sapiens* and can be briefly summarized as follows: Changes in morphology and behavior result in changes in the cultural tool kit that result in changes in nutrition, that in turn result in changes in morphology, that in return result in changes in the cultural tool kit in a never-ending spiral of development.

The evidence from analysis of extant cross-historical research focused on cultural change indicates an uneven process of increasing complexity in societies' "cultural tool-kits," some of which appear to have relatively restricted consequences for cognitive change bound to particular cultural practices, and some of which appear applicable to a broad range of practices producing equally broad cognitive changes (e.g., the development of writing systems). However, levels of cultural complexity are never uniform within societies and do not inexorably undergo increases in complexity. There is, to modify Tomasello's (1999) metaphor, "slippage" in the "ratchet effect" that often characterizes human cultural change.

For the study of culture and ontogeny in modern humans, an approach that combines study of domain-specific and domain-general phylogenetic factors in combination with culturally practice-specific and culturally general factors, appears to provide a systematic way to approach the role of culture in ontogenetic cognitive development. As appropriately pointed out by Keil (2003), it is undeniable that some phylogenetic constraints on development are domain-general. As noted earlier, we also believe that some cultural tools, ideas, tendencies, preferences, and so on serve as constraints across a large number of practices.

When we focus on microgenetic development, that is, cognition and learning at particular phases of ontogenetic development, relevant prior knowledge and general processing mechanisms (e.g., changes in memory capacity, studied by Robbie Case, and operational logic, studied by Jean Piaget) seem to serve as the most powerful constraints. Thus, a number of cognitive developmentalists (e.g., Keil, 2003) assume a 2×2 table of innate–acquired by specific–general processes, which is compatible with the combinations of phylogenetic–cultural and specific–general processes we have adopted here. However, within our framework, prior knowledge and processing mechanisms are emerging products of the interaction between innate and cultural constraints.

An important task for the future is to generalize this approach to a broader range of behaviors, including the connections between cognitive, social, and emotional aspects of development, all of which, we believe, are subject to the general principles invoked in this chapter.

NOTES

1. The wording of this passage reveals an important commonality between the words *means* and *medium* in Russian. The Russian word translated here as *medium* in the phrase "by the medium of which" was almost certainly *sredstvo*, judging from similar statements in other articles written at this time. *Sredstvo* is often translated as "means," particularly in the phrase "by means of which." We note this convergence because the intimate relation between means and media is one of the central theoretical assumptions of the cultural–historical approach.

2. Labor involves more than tool use to overcome barriers to a goal: "In short, the animal merely *uses* external nature, and brings about changes in it simply by his presence; man by his changes makes it serve his ends,

masters it. This is the final, essential distinction between man and other animals, and once again it is labor that brings about this distinction” (Engels, 1960, pp. 290–291, quoted in Vygotsky & Luria, 1993, p. 76; italics in original).

3. Although Beach’s students were in their early 20s and his shopkeepers, in their 40s, this age difference was not the object of his research, and all were treated as adults.

4. The importance of getting an early start on learning to weave reveals itself in the fact that when American psychologists such as Greenfield and Rogoff have sought to learn to weave, one of the major hurdles is the great difficulty they experience being able to maintain the postural position required. This pervasively experienced fact is a clear reminder of how cultural practice shapes biological capacity during ontogeny.

CHAPTER 6

Self as Cultural Mode of Being

SHINOBU KITAYAMA

SEAN DUFFY

YUKIKO UCHIDA

Culturally inspired approaches to psychology have flourished during the last two decades (Bruner, 1990; Cole, 1996; D'Andrade, 1995; Fiske, Kitayama, Markus, & Nisbett, 1998; Greenfield, Keller, & Fuligni, 2003; Lehman, Chiu, & Shaller, 2004; Markus & Kitayama, 1991; Shore, 1996; Shweder, 2003; Triandis, 1995). These approaches have covered a wide range of territory from basic perception and attention (Nisbett, Peng, Choi, & Norenzayan, 2001), emotion and motivation (Kitayama & Markus, 1994; Mesquita & Frijda, 1992), and all the way up to social institutions and organizational behavior (Earley, 1989; Nisbett & Cohen, 1996). Although cultural issues are traditionally studied by anthropologists using ethnography as a primary method, in more recent years they have been examined in increasing quantity and quality by psychologists with their traditional methods of cross-cultural surveys and experiments (e.g., Nisbett & Cohen, 1996). Although informed significantly by ethnographic knowledge, these methods bring to the field more rigorous and consensually verifiable means by which to assess hypotheses suggested by in-depth observations of culture and, moreover, to determine certain boundary

conditions for the hypotheses (Cohen, Chapter 8, this volume).

From the very outset of this psychologically oriented work on culture, the notion of self has been central in defining issues, formulating questions, and theoretically integrating a great variety of empirical findings (e.g., Markus & Kitayama, 1991; Marsella, DeVos, & Hsu, 1985; Shweder & Bourne, 1982; Triandis, 1989). Two fundamental insights have emerged from this analysis. The first is the time-honored idea of the self as a *social product* (Cooley, 1902/1922; Mead, 1934). Humans, in this view, are social and cultural animals (Aronson, 1992; Baumeister, 2005); that is, the self is made possible through symbolically mediated, collaborative social interaction among many individuals in a given cultural community. Second, researchers have begun to realize that the self is best conceptualized as a psychological system for behavioral regulation (Kitayama & Duffy, 2004; Markus & Kitayama, 2004). This system, moreover, is not merely an organization of conceptual schemas on which to reflect back. More importantly, it is providing a principle for one's spontaneous behavioral organization or his or her *modus operandi*. In other

words, the self is a matter of “I” as well as “me” (Mead, 1934).

MUTUAL CONSTITUTION OF CULTURE AND SELF

The idea that “I”—the active agent—is a social product can be articulated most clearly by referring to earlier theorists in the symbolic interactionist school of social psychology such as Mead (1934) and Cooley (1902/1922), according to whom the self is seen as a set of behavioral response tendencies that are coordinated with response tendencies of social others in the cultural community. In early years of life, before children reach school age, social others are limited largely to mothers and other caregivers. But once in school, the child’s world is dramatically expanded to include peers. This added dimension of sociality is likely to serve as a much needed impetus to achieve a generalized conception of how social others in general (i.e., the generalized other; Mead, 1934) act and respond to the self. Patterns of others’ responses are recognized, and response tendencies of the self are thereby coordinated and gradually attuned to the perceived social patterns. From this point on, there is a continuous process of assimilation and accommodation between the self and social others. This interaction between self and others is often mediated by linguistic symbols. It can therefore take the form of dialogue (Hermans, Rijks, & Kempen, 1993). But more generally, this interaction is more behavioral, grounded in daily practices and routines carried out at both verbal and nonverbal levels, and often nondeliberate, and even automatic and unconscious, although it is still fully mediated by symbols.

An outcome of this symbolically mediated social interaction between self and other is the development of a system of action—or agency—that is shaped by and thus closely coordinated with the surrounding cultural environment. Each individual self is very much a collaborative output of the entire cultural community, which provides a matrix of generalized patterns of responses to the self.

The notion that cultural ideas are both reflected in and justified in terms of relevant social practices and institutions is quite old (see LeVine, Chapter 2, this volume, for a historical review). Over a century ago, Max Weber (1904–1906/1958) pointed out that much of the contemporary capitalist social system and

the individualistic ethos associated with it can be traced back to Protestant varieties of Christianity. Referring to this social system as an “iron cage” (p. 123), Weber emphasized the invisible yet highly objective nature of the cultural environment that is socially and historically constructed throughout the modern West. This cultural environment comprises a set of implicit rules that specify, for example, what it means and what it will actually take to succeed or even to survive. People’s behaviors are governed by these rules, thereby transforming the rules into a “brutal” reality of life that in turn constrains and affords people’s further behaviors. Characteristics of the behaviors that are afforded in this way by the Protestant Ethic and the resultant ethos of capitalism include, for example, hard work, personal goal orientation, and task focus. Because these mental features are literally required to survive in the capitalist environment, they are further fostered and reinforced by this environment.

Likewise, Giddens (1984), a British sociologist, proposed a structuration theory of society, wherein the social structure is an emerging property of the minds shaped by that social structure. This mutual influence between society and the mind is also a recurring theme of a theoretical writing of Bourdieu—a French sociologist (1977). More recently, the same idea has been elaborated by Shweder (1991), who reminded us that “psyche and culture . . . make each other up” (p. 73). Likewise a number of psychologists and anthropologists who follow the lead of Vygotsky and his Russian colleagues have argued for the fundamentally social nature of human thought and, by extension, individual agency in general (Cole & Hatano, Chapter 5, this volume), and have analyzed how this agency is constituted by myriad social practices, with a frequent emphasis on linguistic practices and use (e.g., Ochs, 1988).

This diverse array of proposals and analyses in various social science disciplines has converged to suggest that once socialized in a given cultural community, individuals will gradually develop a psychological system of regulating their own thoughts, feelings, and actions in attunement with myriad characteristics of the surrounding sociocultural environment. This psychological system of self-regulation constitutes the person’s *mode of being*—his or her generalized pattern of thought, feeling, and action or standard operating procedures (Triandis, Chapter 3, this volume) employed

for these psychological functions (Kitayama & Duffy, 2004; Markus & Kitayama, 2004). The “mode of being,” therefore, can be defined as a psychological system for action, or simply as agency. These terms are therefore used interchangeably hereafter. Each individual’s mode of being is both constantly afforded and constrained by behaviors, expectations, or evaluations of others.¹ More generally, it is maintained by generalized societal response tendencies or norms shared by others in the community. The emerging patterns of interdependence between one’s mode of being and the generalized responses of the society at large provide the basis for anticipating substantial cross-cultural variations in the mode of being.

DEFINING CULTURE

To begin our analysis of the mode of being, it is necessary to have some tentative agreement about what culture is. Over the course of social science literature, culture has been variously defined (Kroeber & Kluckhohn, 1952/1966; see Borofsky, Barth, Shweder, Rodseth, & Stolzenberg, 2001, for a recent debate on the issue). Yet common in many of the definitions is the notion that culture is a whole set of symbolic resources of a given community, such as lay theories, icons, scripts, and schemas (Adams & Markus, 2004). The symbolic resources of culture are accumulated and transmitted across generations and are usually externalized into social practices and social institutions (D’Andrade, 1995). For example, the cultural idea of God-given human rights is constitutive of many Western democratic social institutions. The same idea is also central in daily practices that emphasize choice (Iyengar & Lepper, 1999). These symbolic resources of culture—both ideas and practices—inform members of the pertinent cultural community of what we referred to earlier as the more general societal response tendencies or norms shared by others in the community.

Culture is dynamic in that cultural ideas and practices are invented, accumulated, and systematically changed over time, both within and across generations (Moscovici, 1984). Culture is also dynamic because cultural ideas and practices have multiple meanings that are constantly in flux, negotiated, manipulated, and arbitrated for a variety of reasons by all individuals who participate in a cultural commu-

nity. For example, practices and ideologies of people of power are often imitated by people of lower rank (Richerson & Boyd, 2005), enabling the former to initiate major cultural, political, and societal changes.

One particularly powerful type of symbolic resources of culture specifies the nature of self and its relationship with others. These ideas, called models of self and relationship (Markus, Mullally, & Kitayama, 1997), deserve special attention in psychology, because they are directly implicated in all psychological processes that constitute the self as agent and its relations with the surrounding social environment. As we have already noted, one cultural model of self and social relations that is especially influential in mainstream American middle-class culture can be traced back to the Protestant Ethic (Kitayama & Markus, 1999). This model distinguishes between the domains of work and social life. Originally, the distinction was grounded in the theological notion of calling—a mission assigned personally by God to the self. The notion of work as calling required the segregation of this domain from other domains, including social relations. Today, however, this segregation of work from social life is conventionalized as a social routine that represents a secular, mostly North American, middle-class work ethic of professionalism (Sanchez-Burks, 2005).² This model and the associated moral imperatives then foster a variety of social behaviors that are highly individualistic, task-oriented, and relatively impervious to socioemotional cues in work settings, and that behaviors become highly consensual within a group of people who share the model.

One important consequence of the fact that cultural models are externalized in social practices is that relevant behaviors are regarded as normative and consensual (D’Andrade, 1995). Thus, they are often taken for granted. Rarely can any doubt be raised about the practices and their underlying assumptions. This applies not only to laypeople but also to the researchers who study them. Comparative methods are therefore imperative in cultural psychological research (Cohen, Chapter 8, this volume). For example, only when a comparison is drawn between middle-class American practices and those in other cultural groups do the historical roots and cultural groundings of the Protestant relational ideology become evident. Only through such comparison can the uniqueness of this cultural model be identified and delineated. In the ab-

sence of such explicit comparisons, culture is typically invisible. Yet, it can be very powerful. As Durkheim (1938/1964) noted, “Air is no less heavy because we do not detect its weight” (p. 5).

CHAPTER OUTLINE

In this chapter, we elaborate on the thesis that cross-culturally divergent modes of being are contingent on cultural ideas and practices. Our emphasis is twofold. First, we hope to articulate two broad types of modes of being, independence and interdependence. Second, we also hope to delineate variable manifestations of these modes of being as a function of regions, social class, and other relevant socio-cultural and historical factors and forces. The chapter consists of three parts.

First, we set up a theoretical framework. We argue that culturally sanctioned patterns of social relations encourage two divergent principles of action organization, which in turn foster correspondingly divergent modes of being; that is, independent social patterns encourage self-directedness, which in turn leads to (1) influence-oriented style of action, (2) self-centricity in self–other representations, and (3) analytic cognition. In contrast, interdependent social patterns encourage social responsiveness, which in turn leads to (1) adjustment-oriented style of action, (2) other-centricity in self–other representation, and (3) holistic cognition.

Second, we review evidence for psychological tendencies associated with the respective modes of being. Our review is organized around three components of the mode of being (i.e., style of agency, self–other representations, and cognition). We show that the three components tend to cohere together when one examines cultures that are historically highly independent (e.g., North American middle-class cultures) or highly interdependent (mainstream East Asian cultures).

In the third part of this chapter we examine developmental and social antecedents of the two modes of being. We first review evidence for systematic cultural shaping of the model of being through socialization, then examine cultures that are neither strongly independent nor strongly interdependent. We argue that the three components of the mode of being are distinct and thus dissociable. The analysis here is necessarily preliminary, because pertinent data

are lacking. Yet we suggest that future effort along this line will allow us to take a focused look at antecedent conditions for the mode of being.

Altogether, we seek to advance a thesis that, through socialization, culture’s symbolic resources are incorporated or appropriated to form a system of behavioral regulation. This system—called the “cultural mode of being”—is thus symbolically mediated, both behavioral and mental, and, moreover, it is an integral part of a larger collective process by which culture is created, preserved, and changed. Thus, a dynamic process of mutual constitution emerges between culture and self. After examining some critical appraisals of the current approach to culture and self, we conclude with some suggestions for future work on the cultural mode of being.

THEORETICAL FRAMEWORK: SOCIAL RELATIONS AND ACTION REGULATION

Our theoretical framework is presented in Figure 6.1. We assume that cultures vary substantially in what patterns of social relations are valued, encouraged, and appropriated to construct daily social interactions at many different levels and spheres. Because the culturally typical pattern of social relations requires disparate principles of behavioral regulation, it promotes correspondingly divergent ways in which social actions are organized, resulting in cross-culturally variable modes of being. It should be kept in mind that the causal sequence may go in the other direction. Thus, a given mode of being highlights the corresponding principle of action organization, which in turn may encourage the respective social relational patterns. In Figure 6.1, this possibility is acknowledged by dotted arrows (for earlier versions of the conceptualization, see, e.g., Kitayama & Markus, 1994, 1999; Markus et al., 1997).

Pattern of Social Relations

Gesellschaft and Gemeinschaft

It goes without saying that there are many different social relations. However, these relations are likely to be classified into a relatively small number of types (Fiske, 1992). According to one prominent line of analysis, there are two

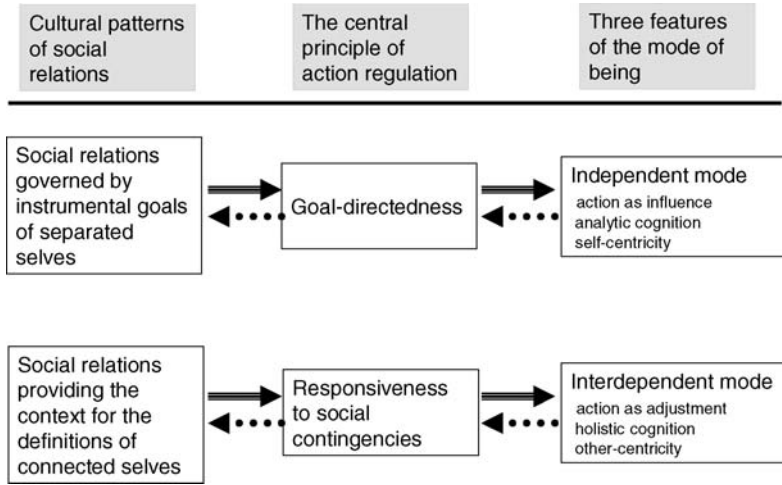

FIGURE 6.1. The theoretical framework: patterns of social relations, the principle of action regulation, and features of the mode of being.

fundamentally different forms of sociality. These forms were referred to by Tönnies (1887/1998)—one of the first proponents of this view—as *gesellschaft* and *gemeinschaft*, respectively. *Gesellschaft* is a form of sociality maintained by instrumental goals of participating individuals, whereas *gemeinschaft* is derived from inherent connectedness of participating individuals. A society created by the consent of like-minded individuals is a typical example of *gesellschaft*, and family and other small-size communities are typical of *gemeinschaft*.

Whereas Tönnies suggested that the two forms of sociality define the most fundamental types, Fiske (1992) has argued for four basic models of social relations. Fiske’s first type, called “communal sharing,” is analogous to *gemeinschaft*. Equality matching encompasses reciprocal exchanges, which can take place in both *gemeinschaft* and *gesellschaft*. Authority ranking implies hierarchical relations, which can also take place in both *gemeinschaft* and *gesellschaft*. Finally, his market pricing focuses on instrumental social relations and thus resembles *gesellschaft*. It would appear, then, that Fiske’s framework adds elements of exchange and hierarchy to the scheme suggested by Tönnies.

Yet another important theoretical scheme by Shweder, Much, Mahapatra, and Park (1997) has proposed that three important classes of moral codes are used to organize social life. The morality of autonomy rests on the idea

that each individual has an inherent value and comes with a set of “God-given” rights. It depicts the person as independent and both fully responsible for his or her own action and valuable in his or her own right. According to this morality, social relations are seen as derivative and thus largely instrumental. They are thus analogous to *gesellschaft* (or Fiske’s market pricing). The morality of community is derived from the idea that community is primary, and duties and obligations vis-à-vis the community are the ultimate arbiter of values and judgments. Therefore, this morality entails social relations that are given or that preexist prior to the emergence or definition of each individual participant, similar to Tönnies’s *gemeinschaft* (or Fiske’s communal sharing).

What is unique in the Shweder et al. (1997) scheme is inclusion of the third class of morality called “divinity,” which emphasizes sacred values associated with supernatural being(s) found in many religions of the world (Atran, Chapter 17, this volume). This third class of morality is distinct from both autonomy and community; moreover, it is associated with a distinct set of emotions (Rozin, Lowery, Imada, & Haidt, 1999). Yet in terms of social relations, it is not clear whether this moral system is instrumental in forging any unique class of worldly social relationships.

In short, it is a reasonable first approximation to suggest that *gesellschaft* and *gemeinschaft* are two of the most basic types of social relations. In fact, analogous typologies have

been repeatedly proposed. Thus, models of social relations analogous to *gesellschaft* have been called independent (Markus & Kitayama, 1991), autonomous (Sampson, 1988), self-oriented (Parsons & Shils, 1951), egocentric (Shweder & Bourne, 1982), exchange (Clark & Mills, 1979), and individualist (Hofstede, 1980; Triandis, 1989). Given this class of models, social relations are formed on the basis of instrumental goals of participating individuals. The other class of models is based on a contrasting assumption that the self is fundamentally connected with others and is in fact embedded and made meaningful within social relationships. These models are referred to as interdependent, connected, socially oriented, sociocentric, communal, and collectivist.

It is important to emphasize that both independent, instrumental, and goal-directed practices, values, and ideas and interdependent, communal, and group-oriented ones are available in all cultures (Fiske, 1992). Moreover, in all cultures, some types of relations (e.g., business transactions) are mostly construed to be goal-oriented and guided by self-interests, whereas some other types of relations (e.g., friendship relations) are mostly construed as communal and relation-centered (Fiske, 1992; Kitayama & Uchida, 2004). However, these two models of social relations are unevenly distributed, and differentially sanctioned and valued across cultures. Thus, the overarching hypothesis is that there is a substantial cross-cultural variation in the relative significance and prevalence of the two forms of social relations.

*Cross-Cultural Variation
in Predominant Forms of Social Relations:
Evidence from Cross-Cultural Value Surveys*

Whereas the foregoing classifications are largely theoretical, during the last three decades there have been numerous attempts to measure cultural values. This literature has discussed the distinction between *gesellschaft* and *gemeinschaft* under the rubric of individualism and collectivism (Hofstede, 1980; Triandis, 1989), and has provided an important clue to the question of whether cultural groups might vary systematically in terms of their relative emphasis on the two values related to both self and social relations (for reviews, see Kağıtçıbaşı, 1997; Smith & Schwartz, 1997).

In 1980 Hofstede published *Culture's Consequences*. In this influential monograph, Hofstede reports results from a survey conducted on 117,000 IBM employees in 40 nations. In one part of the survey, participants were asked to report how important each of 14 work-related values was to them. The researcher first controlled for acquiescence response bias (a tendency to provide affirmative answers regardless of question contents; Smith 2004). By factor-analyzing the mean country scores for the 14 values, Hofstede identified two factors, the first of which is of interest here. This factor had high positive loadings on the tendencies to value (1) personal time outside of work, (2) freedom to choose different approaches in job, and (3) challenges in work. It also had high negative loadings on the tendencies to value (1) training opportunities in work, (2) good physical conditions in work, and (3) full use of one's work skills (Hofstede, 1980, p. 220). One problem with this work is that some of the items have no obvious connections to either individualism or collectivism. Hofstede (1991) argues, however, that *within the work environment in which the survey was conducted*, the discovered dimension can be seen as representing individualism (i.e., a value placed on both personal freedom work obligation and personal initiatives at work) on the one hand, and collectivism (i.e., a value placed on the work environment and, thus, on IBM—the company) on the other.

The Hofstede measure has several problems. First, as already mentioned, not all items would seem obviously related to the constructs unless considered and interpreted in the specific context in which the survey was conducted—IBM workers responding on their work values within the context of their own work environment. Second, country-level indicators of values are enormously noisy; hence, they are unlikely to be completely valid. Third, reported values and attitudes are, after all, what people think and say. But culture's practices, symbols, and institutions are much more than each person's thought contents (Kitayama, 2002). Fourth, some important artifacts can potentially distort survey results. These artifacts include reference group effect (Heine, Lehman, Peng, & Greenholtz, 2002), acquiescence bias (Schimmack, Oishi, & Diener, 2005), and absence of any one-to-one relationship between social values or norms and personal values (Peng, Nisbett, & Wong, 1997). Hence, there is

good reason to be cautious in interpreting the results from cross-cultural value and attitude surveys.

Nevertheless, the Hofstede measure has proved to be valid, often highly correlated with certain cultural or societal characteristics. For example, it is related to other country-level measures of values (Bond, 1988; Inglehart & Baker, 2000; Triandis et al., 1986; Schwartz, 1992). Moreover, it is positively correlated with the Gross National Product (GNP; Smith & Schwartz, 1997), democratization (Inglehart & Baker, 2000), national means of subjective well-being (Diener & Diener, 1995), and even certain linguistic features such as pronoun drop (Kashima & Kashima, 2003; see Diener & Suh, 2000, for a review). It is also important that these country scores correspond closely to expert judgments (Peng et al., 1997). We regard this empirical convergence as impressive, which provides a basis to assume that the Hofstede score of individualism (vs. collectivism) is basically valid as a country-level indicator of individualism and collectivism.

For the present purposes, then, this dimension may be seen as an index of predominant forms of social relations sanctioned in varying cultural contexts. Thus, both Western European countries and the United States are high in individualism (thus *gesellschaft*, or instrumental relations, are encouraged and culturally sanctioned) and many Asian and South American countries are high in collectivism (thus *gemeinschaft*, or communal relations, are encouraged and culturally sanctioned).

In summary, the classic dimension of *gemeinschaft* (collectivism and interdependence) and *gesellschaft* (individualism and independence) has been identified, albeit often implicitly, by numerous researchers in the past as crucial in understanding cultural values (Hofstede, 1980; Inglehart & Baker, 2000; Schwartz, 1992), morality (Shweder et al., 1997), social behavior (Triandis, 1995), social institutions (Parsons & Shils, 1951), and self (Markus & Kitayama, 1991). Moreover, despite some recent claims to the contrary (Oyserman, Coon, & Kimmelmeier, 2002; Matsumoto, 1999; Takano & Osaka, 1999), the cultural variation along this dimension appears both systematic and substantial, often correlated strongly with some distinct cultural characteristics, including GNP, linguistic features, and overall levels of subjective well-being (Hofstede, 1980; Schimmack et al., 2005).

Among others, these data provide evidence that Western Europeans and North Americans are considerably more oriented toward independence and individualism, whereas Asians are considerably more oriented toward interdependence and collectivism.

Principle of Action Regulation

The two forms of social relations discussed earlier authenticate very different principles of action regulation. To participate in instrumental social relations, individuals have to know their goals, desires, needs, and plans, appraise the attendant social situation with respect to these internal attributes of the self, then direct themselves in accordance with the relevant attributes of the self. The central principle of action organization, then, is goal directedness. In contrast, to participate in communal social relations, individuals have to be vigilant with respect to external contingencies, including expectations, desires, and needs of others, as well as a variety of other nonpersonal elements in the attendant social situation, then actively act to adjust their own behaviors to such contingencies. The central principle, then, is responsiveness to social contingencies.

At first glance, self-directedness might seem to give rise to war-like interpersonal states where egocentric Machiavellian strategists try to deceive one another to promote their own interests without mercy for others, whereas social responsiveness might appear to encourage benign welfare-oriented social utopias. This initial impression is both naive and deceptive. In fact, within an instrumental social relationship, individuals have to be chosen by others to benefit from social relations. Social rejection is just as damaging in instrumental relations as in communal relations (Baumeister & Leary, 1995). Moreover, social rejection may present a realistic threat, especially in instrumental relations, because, unlike communal relations, instrumental relations are relatively easy to terminate. Thus, one important class of goals in instrumental social interactions is to be liked and respected by others. In contrast, within a communal social relationship, individuals can be confident that others in the relationship are attentive to their actions, and even their thoughts and feelings. Yet this attentiveness need not be benign. In many interdependent, collectivist societies, therefore, the worst enemy is often imagined to be among one's best

friends (Adams & Plaut, 2003). Thus, in many instances, general trust that people experience and report in respect to social others or the society in general is bound to be higher in independent, individualist societies than in interdependent, collectivist societies (Fukuyama, 1992; Inglehart & Baker, 2000; Putnam, 1993; Yamagishi & Yamagishi, 1994).

Mode of Being

We propose that the cross-culturally divergent principles of action organization (self-directedness and social responsiveness) give rise to differences in three components of self-regulation. In organizing and regulating one's own actions, one has to represent the surrounding environment in which action takes place (*cognition*). Within this environment, one then has to represent both the self and other relevant people (*self–other representation*). On the basis of both the general situational construal and the representation of both the self and others, one then regulates his or her own behaviors (*style of action*). These three elements of self-regulation are coordinated with one another. Yet they are distinct and partially independent. This idea is illustrated in Figure 6.2, where the components are denoted by overlapping circles. Within the respective mode of being, the most typical case can be found at the center, where the three circles overlap. Yet there are many other cases in which one or even two of the elements are missing. We argue later that this analysis allows us to cover a wide range of cultures that are neither strongly independent nor interdependent.

Independent Mode

When culture emphasizes independent, goal-oriented, instrumental practices and ideas in organizing social relations (i.e., *gesellschaft*), one's predominant form of action tends to be the use of his or her own goals, desires, judgments, and other internal attributes in an effort to cause changes in the environment. This form of action has been sometimes called “primary control” (Weisz, Rothbaum, & Blackburn, 1984). Typical examples include behaviors oriented toward personal achievement and attempts at persuading others. Morling, Kitayama, and Miyamoto (2002) have called this mode of action “influence” to emphasize that it involves an effort to cause changes in the environment. Of course, within the influence mode of action, social others are important. But they are considered important only to the extent that they are seen as instrumental in achieving one's own goals and desires. Accordingly, the representations of the self tend to be more emphasized, elaborated, and/or valued than the representations of others. This mode of self–other representation may be said to be self- or egocentric (Shweder & Bourne, 1982) or self-oriented (Parsons & Shils, 1951). Moreover, goal-directedness is likely to foster focused attention toward a goal-relevant object in the environment. This may be the case even when the object at issue is another individual. When a single object is picked up and detached from the immediate context, it is likely to be scrutinized “for its own sake,” categorized in terms of a general taxonomic system. In person perception, for example, a focal person is likely to be categorized in terms of personality taxon-

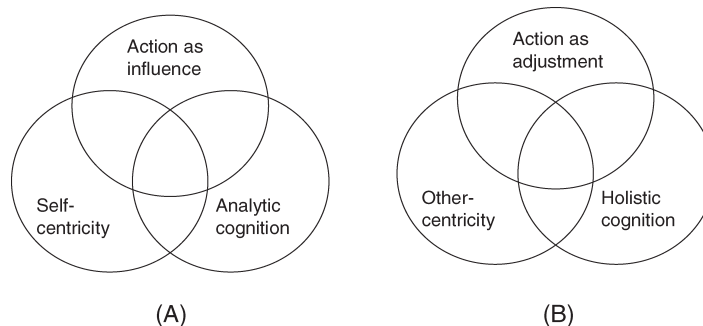

FIGURE 6.2. Varieties of independence (A) and interdependence (B): The respective modes of being comprise three primary features—agency, self–other representation, and cognition. The three features tend to go together, but there may be many exceptions.

omy. Likewise, in object perception, a focal stimulus is likely to be understood in terms of a relevant semantic category. This mode of thought is called “analytic” (Nisbett et al., 2001). In short, the independent mode of being is associated with (1) action as influence, (2) self-centricity in self–other representations, and (3) analytic mode of thought.

There is a general consensus in the literature that the view of the self as independent and the corresponding form of social relation (*gesellschaft*) have their origins in the modern period in Western Europe, although many of the ideas of the modern West can be traced back to the Greek civilization (Nisbett, 2003). Reformation of the Catholic Church and the resulting Calvinist varieties of Protestantism had a major influence on the emergence of the independent view of person (Sanchez-Burks, 2005). So did numerous philosophers of the Enlightenment, including Rousseau, Locke, and Voltaire (Taylor, 1989). Once transplanted in North America through initial waves of Western European immigrants and espoused by the Founding Fathers of the United States, the independent view of the self has since become a cornerstone of mainstream American culture (Bellah, Madsen, Sullivan, Swidler, & Tipton, 1985). As Geertz (1975) noted, North Americans are wedded to the view of the person as “a bounded, unique, more or less integrated motivational and cognitive universe, a dynamic center of awareness, emotion, judgment, and action organized into a distinctive whole and set contrastively both against other such wholes and against its social and natural background” (p. 48). Today this view of the person is embodied in numerous cultural artifacts, mundane practices of daily life, social institutions, and personal values.

Nevertheless, there is likely to be substantial variation within North America in the degree to which people subscribe to the independent view of the self. One can expect considerable ethnic variations, such that the independent mode of being may be most clearly identified among Americans of Western European descent. Moreover, to the extent that self-direction is related to job complexity (Schooler, Chapter 15, this volume), the independent mode of being may be less pronounced for working-class people, whose jobs are bound to be more routinized, not requiring flexible thought, and are thus less complex. Moreover, the same consideration might suggest that the independent mode of being may be identified in

many other regions of the world. For example, middle-class individuals in industrialized societies may show some sign of independence in part because their jobs require a greater extent of self-directedness, flexible thinking, and autonomy.

Interdependent Mode

When culture emphasizes interdependent, other-oriented communal practices and ideas in organizing social relations (i.e., *gemeinschaft*), one’s predominant form of action tends to be the consideration of expectations, desires, and needs of others in an effort to adjust one’s own actions to these intentional states attributed to the others. This form of action, most typically characterized in terms of its responsiveness to concerns and expectations of others, and more generally to a variety of social contingencies, has sometimes been called “secondary control” (Weisz et al., 1984). Typical examples include behaviors oriented toward concerns of others and attempts at conforming to and gratifying others. Morling and colleagues (2002) have called this mode of action “adjustment” to emphasize the fact that this mode involves an effort to accommodate one’s own behaviors in accordance with contingencies that present themselves in social relations.

Within the adjustment mode of action, others are centrally important. In fact, selves are often defined and made meaningful in respect to such others. For example, most social roles, such as child, parent, teacher, and student, can be defined only in reference to pertinent social others. Likewise, even seemingly purely private attributes, such as opinions and judgments, may also be defined in such relational terms. For example, one might agree or disagree with others. Or one might identify him- or herself with someone else in a particular domain. Interdependence does not necessarily imply obedience and conformity. In fact, many forms of rebellion also presume a tightly knit relationship with powerful others. In all these cases, because the self is defined in reference to social others, the cognitive representations of these others are likely to be at least as elaborated, highlighted, and often valued as the cognitive representations of the self. In this sense, this mode may be said to be sociocentric (Shweder & Bourne, 1982) or socially oriented (Parsons & Shils, 1951). Moreover, responsiveness to social contingencies is likely to foster holistic attention—that is, attention that is dispersed to

many potentially significant elements of the environment. This may be the case even when the elements at issue are other individuals. When individuals attend to many such elements simultaneously, they are likely to be understood within a holistic scheme. Instead of characterizing each of many individuals involved in terms of their unique personality traits, one may come up with a broader schema of the relationship or the group as a whole that encompasses all the individuals involved. This mode of thought is called “holistic” (Nisbett et al., 2001). In short, the interdependent mode of being is associated with (1) action as adjustment, (2) sociocentricity in self–other representations, and (3) holistic mode of thought.

It is generally agreed that in many societies outside the West, the self is inherently more social, connected with others and immediate communities. In fact, throughout much of the history of human existence, social relations have predominantly been kin-based and relatively stable (Brewer, 2004; Richerson & Boyd, 2005; Konner, Chapter 4, this volume); moreover, they are limited to relatively small groups of up to 80 at most (Dunbar, 1996). These considerations suggest that the interdependent mode of being, which is defined primarily in terms of its connectedness with others and its immersion in a community, may have been common for much of its history for the human species (Konner, Chapter 4, this volume). If true, this substantially reduces the burden of explaining the origins of cultural differences, with a main emphasis to be placed on the emergence of the independent mode out of the interdependent mode. Some possible hypotheses include modernization (Inglehart & Baker, 2000), voluntary settlement (Kitayama, Ishii, Imada, Takemura, & Ramaswamy, 2006), and wealth (Triandis, 1995).

Nevertheless, even if the interdependent mode is primordial, defining some sort of default form of sociality for humans, this by no means implies that cultures outside of the modern West are entirely homogeneous. To the contrary, it is likely that different types of interdependence existed throughout history and over different geographic regions (Fiske et al., 1998). For example, a deep commitment to immediate family of Chinese is clearly different than the Moroccan way of defining the self in terms of birthplaces (Geertz, 1973). Likewise, whereas a founding ideology for Chinese society, Confucianism, emphasizes virtues of adhering to hierarchical social relations, there is a much stronger egalitarian,

communal emphasis in hunter–gatherer groups in Africa (Fiske, 1992) and Australia (Myers, 1986). Moreover, collectivism of Confucian cultures regards personal positive affect as a hindrance of social harmony, but collectivism of Latin cultures appears to use positive affect as a glue of social relations (Cohen, Chapter 8, this volume). Nevertheless, in all these cases, the primary commitment is to a social unit of which the self is part. The self is ascribed to the unit and often is deeply connected and attached to it. The self’s belongingness to the group is taken largely as given, not as chosen for his or her own instrumental goals or considerations. Accordingly, along with massive differences, a set of common themes or features may cut across many of the interdependent societies and communities.

EAST–WEST DIFFERENCES IN MODE OF BEING

Much of the evidence for the two modes of being comes from systematic cross-cultural comparisons between North American middle-class populations and East Asian populations. This evidence suggests that whereas East Asians show a predominantly interdependent mode of being, middle-class North Americans exhibit a predominantly independent mode of being. These two cultures can be characterized by the completely overlapping area of Figure 6.2. In what follows, we review evidence for each of the three components of the mode of being. Our review is more thorough and comprehensive for the style of action component than for either the self–other representation or the cognition, because the latter two domains are covered in full in other chapters by Heine (Chapter 29, this volume) and Norenzayan et al. (Chapter 23, this volume), respectively.

Style of Action

The first component of the mode of being involves a style of action as either influence or adjustment. Whereas self-directedness fosters influence, social responsiveness promotes adjustment.

Prevalence and Consequences of Influence and Adjustment

In an influential article, Weisz and colleagues (1984) reviewed a variety of cultural practices and customs of both American and Japanese

cultures. In North America, many more practices highlight the self (thereby allowing one to stand out and act in accordance with one's own judgments), and the corresponding values and beliefs in self-directedness and active effort to cause changes to happen in the environment (called "primary control"). In contrast, in Japan many more practices encourage the self to conform to expectations or needs of others (thereby adjusting oneself to these expectations or needs), and the corresponding values and beliefs in social sensitivity and attunedness (called "secondary control"). *Secondary control* is a misnomer, because this mode of action is just as agentic as the mode called primary control; moreover, it is no less primary in Japan. Morling, Kitayama, and Miyamoto (2002) therefore call the two styles of action "influence" and "adjustment," respectively.

To see whether this cultural difference is prevalent in practices involving influence and adjustment, Morling and colleagues (2002) asked both North Americans and Japanese to remember the most recent instance in which they either "influenced the surrounding" or "adjusted themselves to the surrounding." They then asked the participants to indicate how recently the remembered event took place. If a given class of events is frequent, they should occur in the more recent past. As predicted, the latest influencing episode was less than a day old in the United States, but it was several days old in Japan. This cross-cultural difference was completely reversed for the adjusting episodes.

What are the consequences of acts of influence or adjustment relative to self-perception? Two dimensions of self-perception are especially relevant. First, efficacy, esteem, or power of the self (or self-esteem) is a central defining feature of the sense of the self as independent (Heine, Lehman, Markus, & Kitayama, 1999). Because the act of influencing is an expression of self-esteem, it may be predicted that individuals would feel empowered and thus report enhanced self-esteem when they engage in an act of influence. This effect, however, may depend on culture. Because influencing behaviors are culturally sanctioned in North America to a far greater extent than in Japan, the effect of an influencing act on self-esteem may be predicted to be more pronounced in North America than in Japan. The second relevant dimension of self-perception concerns the sense of connectedness to others. Because an act of adjusting is an expression of one's commitment to a rela-

tionship and the value one attaches to it, it may be predicted that individuals feel more connected when they engage in an act of adjustment. Moreover, because adjusting behaviors are more culturally sanctioned in Japan than in North America, this effect of adjustment on perceived connectedness of self may be predicted to be greater in Japan than in the United States.

These predictions received support in another study by Morling and colleagues (2002), who first collected many episodes of both influencing and adjusting from both American and Japanese participants. New groups of both American and Japanese participants were then presented with a randomly selected subset of the episodes thus collected. They were asked to imagine that they engaged in each act described in each episode, and to report how they would feel on dimensions of (1) self-esteem (self-efficacy, esteem, and power) and (2) perceived connectedness with others. The results lend support to the preceding analysis. When engaging in American-made influencing acts, Americans felt quite empowered, reporting enhanced self-esteem. Although a comparable empowering effect of influence was found in Japan, the effect was much weaker. In contrast, when engaging in Japanese-made adjusting acts, Japanese participants reported a strongly enhanced sense of interpersonal connectedness. Furthermore, in line with the foregoing analysis, a comparable connection-enhancing effect of adjustment was virtually nonexistent in the United States.

Interestingly, Americans reported an enhanced sense of connectedness when they engaged in American-made influencing acts. This latter finding suggests that acts of influencing in North America provide a culturally sanctioned way to interpersonally relate to others. Americans often relate to others by arguing or debating, persuading, and proactively helping others. Persuasion defines a major genre of interpersonal relations in all spheres of American life. Even conflicts and interpersonal tensions are often believed to be generative (Rothbaum, Pott, Azuma, Miyake, & Weisz, 2000). These acts are obviously interpersonal, yet they involve a form of influence. Influence thus provides a way in which separated selves are related to one another without compromising the ever-important sense of the self as independent and separate. There was no evidence that influence has such a connecting function in Japan.

The thesis that Americans use social influences to connect to others has received addi-

tional support from recent research by Taylor and colleagues (2004), who show that Americans are much more likely than Asians and Asian Americans to seek support. The explicit solicitation of support is a form of influence; thus, it fits neatly into the default mode of social relations for Americans. Notice that as long as support is explicitly sought, any helpful acts Americans might receive as a consequence are unlikely to compromise their sense of self as independent and self-sufficient. Instead, they are likely to signify the self's interpersonal efficacy, as shown by Morling et al. (2002) in the previously cited work. In contrast, Taylor and colleagues (2004) suggest that Asians do not explicitly seek support from others because of relational concerns, such as causing trouble to the others.

All research available to date on influence is concerned with relations involving peers and friends. It might seem plausible that Asians also seek to influence others as long as these others are lower in social status and rank. Alternatively, even in hierarchical relationships, Asians might seek to avoid explicit forms of influence in part because those in lower in status or rank (e.g., subordinates, children, etc.) might willingly adjust to the expectations of those higher in status and rank. At present, no empirical work exists on this question.

Self-Images and Dissonance

Influence and adjustment as alternative principles of agency may result in quite different concerns about the self. Whereas individuals operating on the principle of independence and influence are concerned with efficacy, competence, moral integrity, and other internal qualities of the self, those operating on the principle of interdependence and adjustment are concerned with what social others might think about the self's qualities. Recently, this analysis has been applied to cognitive dissonance.

Drawing on theories of dissonance process that emphasize the role of self (Aronson, 1968; Steele, Spencer, & Lynch, 1993), Kitayama, Snibbe, Markus, and Suzuki (2004) suggested that dissonance can take cross-culturally divergent forms, because cultures emphasize different aspects of self. In independent cultural contexts, such as North American cultures, private self-images, such as the self's competence and moral integrity, are highlighted; as a consequence, individuals are hypothesized to experience dissonance when their behavioral choice

poses a threat to a certain private self-image they wish to sustain. For example, a choice between two equally attractive cars can raise a threat to one's competence as a wise decision maker and consumer, because the chosen car might have negative features and/or the rejected car might have positive features. Kitayama and colleagues have called this "personal dissonance." In contrast, in interdependent cultural contexts, such as many Asian cultures, public self-images, such as the self's reputations and social acceptance, are highlighted; as a consequence, individuals experience dissonance when their behavioral choice poses a threat to a certain public self-image they hope to maintain. For example, having chosen to buy a luxurious German car might raise a concern about what one's colleagues and neighbors might think about the self. This has been called interpersonal dissonance.

Whether personal or interpersonal, dissonance is an aversive emotional state that motivates the person to justify the original choice (Festinger, 1957). Thus, once induced to experience dissonance, individuals are motivated to justify the act of positively choosing one item by increasing their liking for it and/or justifying the act of giving up another item by decreasing their liking for it. Nevertheless, the foregoing theoretical framework suggests that, depending on the cultural contexts of the person at issue, the dissonance is likely to be aroused under quite different circumstances.

One critical variable is an awareness of "eyes of others" watching and closely monitoring the self (Imada & Kitayama, 2006; Kitayama et al., 2004). Because personal dissonance hinges on what one's choice would mean to one's private self-image, it should happen in total privacy, in the absence of the eyes of others. In contrast, interpersonal dissonance hinges on what one's choice might mean to one's public self-image. For this dissonance to arise, the choice would have to be perceived as public. In fact, if the choice is believed to be completely private, it entails no ramifications for one's public self-image. Under these conditions, there should be little or no dissonance effect.

To test these ideas, Kitayama and colleagues (2004; Imada & Kitayama, 2006) had both American (mostly white, middle class) and Japanese participants (living in Kyoto) choose between two equally attractive CDs and examined the degree to which liking for the chosen CD increased and that for the rejected CD decreased. A key manipulation involved a poster

that, seemingly prepared for a conference presentation, contained several schematic faces that were “watching” whoever was seated right in front of it. In an eyes-of-others condition, this poster was surreptitiously placed so that participants were exposed to the schematic faces. Although no one raised any suspicions about the poster, Kitayama and colleagues (2004) drew on previous work on automatic information processing (e.g., Baldwin, Carrell, & Lopez, 1990), and predicted that the watching eyes of others would covertly, yet powerfully, evoke public self-image concerns among Japanese. In a control condition, no poster was placed before participants.

In support of the foregoing analysis, Japanese participants did not show any dissonance effect in the control condition, but they did show a reliable dissonance effect in the “eyes-of-others” condition. This suggests that in making a choice, the Japanese worry mostly about what the choice might mean to their public self-image. A dissonance effect for them can therefore happen only when these public self-image concerns are engaged. In contrast, Americans showed a strong dissonance effect in the control condition. But this effect was reduced in the eyes-of-others condition. Imada and Kitayama (2006) replicated this effect and proposed that Americans assume that others try to influence them and, as a consequence, watching eyes of others are perceived to constrain their choice. Alternatively, the eyes might have provoked a degree of reactance (Brehm, 1966). In either case, choice under these conditions is perceived as externally constrained and less free, entailing a lesser threat to one’s private self-images and a lesser need for self-justification. In support of this proposal, Imada and Kitayama have shown that a strong dissonance effect remains even when faces are presented, as long as the faces look weak and submissive (thus, unlikely to exert any unwanted influences). This pattern of findings suggests that in making a choice, Americans worry mostly about what the choice might mean to their private self-image. Only to the extent that this anxiety affects one’s private self does a dissonance effect accrue for Americans.

Another recent series of studies has provided further evidence for the present analysis. Hoshino-Browne and colleagues (2005) proposed that a strong interpersonal dissonance (an interpersonal worry resulting from a threat to one’s public image) can result

from a choice one makes for one’s friend. But this effect should be observed only for those who hold quite strong public self-image concerns (e.g., Asians), not for those who do not worry much about public self-images (e.g., European Canadians). As predicted, a justification effect subsequent to a choice made for a friend was significantly larger for Asian Canadians and Japanese than for European Canadians.

Researchers have argued that dissonance represents a threat to the personal self; thus, an affirmation of the personal self should readily eliminate self-justification (Steele, 1988). This prediction has been borne out in many studies. Yet, if the dissonance experienced by Asian Canadians is interpersonal rather than personal in nature, the affirmation must be directed at the interpersonal (rather than personal) self for it to be effective in eliminating the dissonance. In a typical self-affirmation manipulation, participants are asked to circle all values that they personally shared. In addition to this personal affirmation manipulation, Hoshino-Browne and colleagues (2005) used an interpersonal affirmation manipulation in which participants were to circle values their families shared. As predicted, the dissonance effect of Asian Canadians in the friend choice condition was significantly weaker in the interpersonal affirmation condition than in a no-affirmation control. The finding from the personal affirmation condition was quite noteworthy. It turned out that this affirmation manipulation was quite effective if the Asian Canadians were fully acculturated in Canada and identified themselves with the Canadian mainstream culture. No such effect was evident among nonacculturated Asian Canadians.

Intrinsic Motivation

The personal dissonance process just discussed suggests that choice is an integral part of behavioral motivations for Americans. In agreement with this analysis, self-determination theory has suggested that through choice and autonomous engagement in an activity, one’s intrinsic motivation is enhanced (Deci & Ryan, 1985; Lepper & Greene, 1978). For interdependent agents, however, it may be choice made by ingroup members that engages the intrinsic motivation of the person at issue. Such a choice conveys to the person high expectations and hopes held by the others with regard to the

performance of this person. Consistent with this analysis, several observers of Asian cultures have noted that achievement in Asia is often motivated by feelings of indebtedness to parents. Thus, a desire to return obligations to them and to erase any sense of guilt or shame is a major source of personal strivings for excellence (DeVos, 1983; Yang, 1986).

In support of this analysis, Iyengar and Lepper (1999) had European and Asian American children work on a video game involving spaceships. One group of children were allowed to choose the color of their own spaceship. A second group of children were assigned one color by the experimenter; finally, a third group of children were told that their mother chose the color of the spaceship for them. As may be predicted by both our analysis of independent agency and self-determination theory, white children performed much better when they made the choice by themselves than when the color was assigned by the experimenter. Their performance was worst when their mothers made the choice for them. In contrast, as predicted by our analysis on interdependent agency, Asian American children performed better when their mothers made the choice than when either they made their own choice or the experimenter assigned the color.

The motivation to improve the self to meet high expectations held by significant others has been called "self-improvement" (Kitayama, Markus, Matsumoto, & Norasakkunkit, 1997), which involves identification of one's own shortcomings and deficits *via-à-vis* collectively shared high expectations and standards, and an assessment of one's own performance in comparison to such high expectations or standards. It is the experience of deficit or shortcoming that strongly motivates the person to improve. In a recent series of experiments, Heine and colleagues (2001) observed that in an intellectual competence task, Japanese participants were most motivated to persist in the task when they were led to believe they had failed rather than succeeded in a similar task. This pattern was in stark contrast with the pattern observed for Americans, who persisted much more after success than after failure.

Lay Theories of Agency

Do individuals have naive beliefs about actions that are in line with their respective modes of being as independent or interdependent? Our

analysis suggests that North Americans would see another person's act as a form of influence and, as a consequence, would look for internal events that motivated the person to engage in the act. A voluminous social psychology literature on causal attribution has provided ample evidence for the American tendency to focus on internal cause of action, while ignoring potentially available external causes. This effect is so pervasive that it has been called the "fundamental attribution error" (Nisbett & Ross, 1980; Ross, 1977). In contrast, Asians would see another person's act as a form of adjustment and, as a consequence, would immediately look for external events that prompted the person to engage in that act. Hence, the fundamental attribution error may be attenuated or even nonexistent in cultures organized around an alternative view of the self as interdependent (Markus & Kitayama, 1991; Nisbett, 2003).

Since a pioneering study by Miller (1984), this cross-cultural prediction has received substantial support (Choi, Nisbett, & Norenzayan, 1999; Norenzayan, Choi, & Peng, Chapter 23, this volume). Morris and Peng (1994), for example, presented to both American and Chinese respondents various pictures of a number of fish swimming in different formations. When asked for reasons explaining the movement of a central fish, Americans were more likely to refer to internal factors of the fish (e.g., its psychological dispositions) than to factors external to it (e.g., movements of other fish that are present) as a causal factor underlying the fish's movement. In contrast, Chinese respondents were more likely to refer to external factors than to internal factors in the same task. The same cross-cultural difference has been observed in content analyses of media materials (Morris & Peng, 1994) and commentaries on professional sports events (Lee, Hallahan, & Herzog, 1996).

The dispositional bias in attribution implies that individuals are relatively impervious to external or situational factors. Thus, when observing another person behaving under a social constraint, individuals may be expected to ignore the social constraint and instead infer directly from the person's behavior a disposition that corresponds to the behavior (Jones, 1988). This bias, called the "correspondence bias," has been demonstrated among Americans even when the social constraint is quite salient, or

when the action is seemingly nondiagnostic at all of the disposition at hand (Gilbert & Jones, 1986). Under these conditions, however, Asians show very little evidence for correspondence bias (Choi & Nisbett, 1998; Masuda & Kitayama, 2004; Miyamoto & Kitayama, 2002).

For example, Masuda and Kitayama (2004) tested participants in pairs. One participant was assigned an inducer role and the other, an observer role. The task of the inducer participant was to choose one of two essays and give it to a third participant, who in turn read the essay. Both the inducer and the observer were to observe the third participant read the essay and report an impression of him or her. The inducer participant was then given two alternative essays that argued for one or another position on a socially controversial issue at the time (e.g., the nuclear testing France carried out in the Mururoa Coral Reef), and asked to choose one and to give it to the third participant. Both the inducer and the observer subsequently saw a video of the third participant reading the essay and estimated the real attitude of this person on the social issue at hand. Notice that under these conditions, it is very clear that the third participant did not actively choose the essay; nor did he or she write it. Moreover, the social pressure the inducer exerted on the target person is also very clear. Conceptually replicating an earlier study by Gilbert and Jones (1986), Masuda and Kitayama (2004) found that Americans still inferred that the target person's attitude corresponded to the essay content. This very strongly illustrates how robust this dispositional bias in fact is among Americans. As predicted, however, Japanese respondents showed no correspondence bias. They acknowledged the nature of social constraints imposed on the target person and made adjustments for them in estimating his or her real attitude.

Lay Theories of Happiness

If the mode of being is different along with common lay theories of agency that go with it, people may appraise their lives in the correspondingly divergent fashion. Accordingly, although happiness as a general positive emotional state is widely acknowledged in all known cultures (Mesquita & Fridja, 1992), underneath this general proposition might be profound cross-cultural differences in lay under-

standings about happiness. Kitayama and Markus (2000) have suggested that in North America, happiness is typically construed as a personal achievement. Thus, individuals strive to attain happiness and, once obtained, happiness affirms the worth of the internal, private self. In contrast, according to Kitayama and Markus, happiness in Japan is more socially anchored. It is seen as a realization of social harmony or state of mutual sympathy and understanding.

Evidence for this proposal comes from a recent study by Uchida and Kitayama (2006), who asked both American and Japanese participants to describe as many "features, effects, or consequences of happiness" as they could. A large number of features collected in the respective cultures were printed on separate index cards. A stack of cards was then presented to another group of participants within each culture. These participants were asked to sort the cards according to perceived similarities of the descriptions. On the basis of these data, Uchida and Kitayama computed the likelihood of each pair of descriptions to be classified into the same pile. This likelihood (an index of perceived similarities among the features of happiness, varying between 0 and 1) was used to compute a multidimensional scaling solution. In both cultures, three types of descriptions were commonly found: general hedonic states (e.g., joy, excitement, and positive attitude), personal achievement (e.g., getting a good grade, getting a job) and interpersonal harmony (e.g., getting along with others, having a party for a friend).

In support of the Kitayama and Markus (2000) hypothesis, Uchida and Kitayama (2006) observed in the American sorting data that the descriptions related to personal achievement were much more likely to be classified into the general hedonic state pile than were those related to interpersonal harmony. This suggests that positive hedonic experience of happiness is most closely associated with personal achievement for Americans. In contrast, the Japanese associated the general hedonic state of happiness to a far greater extent with social harmony than with personal achievement. Thus, social harmony and interdependence are the crucial element of the Japanese understanding of happiness. Results of several studies that examine correlates of happiness and life satisfaction (e.g., Kitayama, Markus, & Kurokawa, 2000; Kwan, Bond, &

Singelis, 1997; Oishi & Diener, 2003) are consistent with this analysis (see Diener & Tov, Chapter 28, this volume; Uchida, Norasakkunkit, & Kitayama, 2004 for reviews; also see the section on health and well-being).

Emotional Consequences of Style of Action

Kitayama and colleagues (2000; Kitayama, Markus, & Matsumoto, 1995; Kitayama, Mesquita, & Karasawa, 2006) pointed out that some emotions are closely associated with either independence or interdependence. Emotions associated with an accomplishment of independence (including pride, self-confidence, and feelings of superiority) are called “socially disengaging positive emotions.” Emotions associated with a failure in independence and an attendant motivation to restore the tarnished independence (including anger, frustration, and sulky feelings) are called “socially disengaging negative emotions.” Likewise, socially engaging emotions include both positive emotions, which result from success in tasks of interdependence (e.g., friendly feelings, close feelings, and respect), and negative emotions, which result from a failure in tasks of interdependence and accompany a motivation to restore tainted interdependence (e.g., guilt, shame, and feelings of indebtedness).

In a recent series of studies, Kitayama, Mesquita, and Karasawa (2006) asked both American and Japanese participants to report how intensely they experienced a number of emotions in each of many different social situations. They found, as should be predicted, that emotions are intensely experienced only when they share the pleasantness with the attendant situations. But more importantly, among the emotions matched in pleasantness to the situations, the intensity of experience depended very much on each emotion’s social orientation (engaged vs. disengaged). As predicted by the notion that Americans and Japanese seek independence and interdependence, respectively, Americans reportedly experienced disengaged emotions more intensely than engaged emotions, but Japanese reportedly experienced engaged emotions more intensely than disengaged emotions. The cross-cultural difference was quite sizable, with Cohen’s *d* ranging between 1.0 and 1.5.

Further evidence for the hypothesis that emotional experiences are organized in a way that promotes one of the two predominant

modes of being comes from a recent study by Mesquita et al. (2005), who asked both Japanese and Americans (college students and adults from local communities) to provide detailed accounts of their experience of pride, humiliation, and anger. Through a systematic coding of these accounts, they found that the two cultural groups varied widely in many facets of the emotional experience. For example, when feeling pride, 80% of Americans willingly took responsibility for the positive event at issue, but only 37% of Japanese did so. Instead, a majority of Japanese (61%) in the midst of the pride episode remained self-critical by reminding themselves that there was room for further improvement—a tendency rarely observed among Americans. In anger experiences, whereas Americans tended to be strongly inclined to affirm and to justify themselves while feeling aggressive toward the offender, the Japanese were much more likely to report sympathy toward the offender. Although seemingly quite benign, this sympathy might often be close to contempt; that is, we suspect that the sympathy in a case like this might often be based on a perception of the offender as having no chance or hope for betterment, thus being unworthy of even minimal respect. This sympathy—which is close in nuance to “pity” without an overtly pejorative attitude toward the offender—might therefore be a socially desirable way of expressing the contempt. Finally, when humiliated, Americans were reportedly motivated to reaffirm the self and even to become aggressive; Japanese reportedly took responsibility for the incident and announced their intention to improve in the future. Overall, then, the experience of emotion appears to unfold in ways that establish or otherwise restore both positivity and separation of the self among Americans, but it does so in ways that further protect, and breed connectedness and better acceptance of the self by ingroup members among Japanese (Mesquita & Leu, Chapter 30, this volume).

Motivational Consequences

One classic way to assess motivation is to measure frustration that is experienced when one’s motivation is blocked (Berkowitz, 1989). In a well-conducted field experiment, for example, Harris (1974) demonstrated that people in a waiting line are highly frustrated (often resulting in aggressive behaviors) when someone cuts

into the line (thereby interfering with their goal attainment), and this was especially so when they were near the beginning (as opposed to the end) of the line. When people are near the beginning of the line, the goal gradient is assumed to be quite steep, and the drive toward the goal is high.

If North Americans are motivated toward independence and Asians, toward interdependence, such motivational differences should be revealed in the conditions in which people in different cultures feel constrained or frustrated; that is, people experience a degree of restraint and feel that they “cannot do what they want to do” when a key cultural motivation, such as that toward personal control and independence for Americans, and that toward social harmony and interdependence for Japanese, is blocked.

In a recent study that used a large-scale cross-cultural survey, Kitayama and colleagues (2006) measured the sense of constraint with a scale designed to assess the degree to which people chronically experience constraint (the Perceived Constraint Scale; Lachman & Weaver, 1998; Pearlin & Schooler, 1978). As predicted, Americans reported that they “could not do what they wanted,” thus showing a substantive degree of constraint in their life, especially when they were low in personal control. This replicates a large body of literature that attests to the central significance of personal control (Lachman & Weaver, 1998). In contrast, Japanese subjects reported that they “could not do what they wanted,” thus showing feelings of constraint, especially when they were high in relational strain. Importantly, the effect of relational strain or relational harmony was relatively weak for Americans, indicating that Americans are not motivated as much in these relational tasks. On the contrary, the effect of personal control was quite weak for Japanese subjects, showing that they are not motivated as much in this personal task.

Consequences on Health and Well-Being

Because North Americans are strongly motivated toward personal control and independence in general, they may be expected to achieve well-being and health through realizing their independence, that is, by maintaining and enhancing personal control. Although important, promotion of relational harmony or avoidance of relational strain is considered to be more discretionary. In fact, such relational

goals are often secondary, particularly when they are in direct conflict with the personal goals of attaining the sense of control and mastery (Heckhausen & Schulz, 1999). Several studies have demonstrated that a strong sense of personal control is positively predictive of well-being and health in the United States (e.g., Heckhausen & Schulz, 1999; Lachman & Weaver, 1998). In addition, the sense of personal control is likely to yield a strong sense of self-worth or high self-esteem. A large number of studies have shown that self-esteem, and an attendant tendency to self-enhance through social comparison, are major predictors of well-being among Americans (e.g., Diener & Diener, 1995; Kwan et al., 1988; Taylor & Brown, 1988; Uchida et al., 2004; Zuckerman & O’Loughlin, 2006). Likewise, positive feelings based on personal success, such as pride and feelings of superiority, are highly associated with general happiness among Americans (Kitayama et al., 2000, 2006). Additionally, Oishi and Diener (2003) reported that attaining personal goals (e.g., doing what one wants to do) leads to enhanced well-being among European Americans (see also Sheldon & Kasser, 1998).

In contrast, Japanese are motivated toward relational harmony and, therefore, interdependence in general. Thus, we may expect that they will achieve well-being and health by realizing their interdependence, that is, by promoting relational harmony and/or avoiding relational strain (Morling et al., 2002; Morling, Kitayama, & Miyamoto, 2003). Although important, attaining and maintaining the sense of personal control and mastery is not considered essential or primary. Indeed, especially when they are in direct conflict with relational concerns and goals, mastering and control must be subordinate to the ever-important interdependent concerns and goals. Those failing to subordinate them are often considered as immature and childish (Lebra, 1976; Kondo, 1990). As might be expected, well-being in East Asian contexts is strongly predicted by social relational factors, such as social harmony (Kang, Shaver, Min, & Jin, 2003; Kwan et al., 1997); attainment of relational goals (Oishi & Diener, 2003); socially engaging emotions, such as friendly feelings and communal feelings (Kitayama et al., 2000; Kitayama, Mesquita, & Karasawa, 2006); and perceived emotional support from close others (Uchida et al., 2004). The hypothesized link between relational har-

mony and well-being among Asians has also been suggested by the finding that attainment of relational goals (e.g., meeting expectations of significant others) is closely related to enhanced well-being among Asian Americans and Japanese but not among European Americans (Oishi & Diener, 2003).

In a recent cross-cultural survey, Kitayama, Karasawa, and colleagues (2006) tested adult, non-college-student samples in both the United States and Japan, using a large number of self-report measures in health and well-being, and provided additional evidence for the foregoing line of analysis. First, personal control proved to be a reliably more significant predictor of well-being among Americans than among Japanese. This is consistent with several recent findings that demonstrate the significance of self-esteem in predicting well-being in individualistic cultures such as the United States (Kwan et al., 1997; Uchida et al., 2004). In contrast, in Japan, the absence of relational strain most powerfully predicted the summary index of well-being. This finding is consistent with the hypothesis that in the Japanese, interdependent cultural contexts, responsiveness to others, and attendant social harmony are strongly valued and sanctioned. Interestingly, however, the researchers found that avoidance of social tension and strain, rather than promotion of social harmony per se, was most predictive of well-being. This finding is in line with a greater prevention (rather than promotion) focus demonstrated for Asians (Elliot, Chirkov, Kim, & Sheldon, 2002). For example, recent studies have indicated that behaviors of people in Japanese and other Asian contexts are strongly motivated by certain avoidance goals, such as a desire to reduce interpersonal anxiety (Kitayama et al., 2004) and to avoid failure (Heine et al., 2001).

Self, Other, and Relationship

The second of the three components of the mode of being concerns representations of self, social others, and the relationship between the two. Whereas self-directedness and the resulting propensity to influence the external environment encourages people to elaborate and value the representations of the self (their own goals, attitudes, values, and opinions), social responsiveness and the resulting tendency to adjust to the environment encourages people to elaborate and value both representations about

social others and their relationship with these others.

Self-Enhancement

If the self is more central and salient than others, the self may receive a greater symbolic value than do others. But if others are more salient and central than the self, relatively more value is given to the others than to the self. The substantial literature on positive self-uniqueness speaks to this issue. A number of studies have found that North Americans judge themselves to be positively more unique than social others (Kitayama et al., 1997; Heine et al., 1999). For example, when asked to estimate the proportion of others who are better than themselves, the average responses are consistently lower than the midpoint (50%), indicating that North Americans tend to underestimate the number of people who are better than themselves. In a review of cross-cultural studies pertaining to this effect, Heine and Hamamura (2007) observed that this effect is consistently larger for Americans than for Asians. Whenever exceptions were found for this general trend (e.g., Brown & Kobayashi, 2002; Sedikides, Gaertner, & Toguchi, 2003), researchers used a particular format of asking respondents to estimate whether the self is better than an abstract representation of social others, such as “average student” and “typical member.” Yet it has been demonstrated that even other individuals are often perceived to be better than either the average other or the typical other, due perhaps to the fact that the terms *average* and *typical* are somewhat derogatory. Heine and Hamamura (2007) therefore suggest that the apparent exceptions found in the literature are entirely consistent with the general hypothesis that the positive self-uniqueness effect is substantially stronger for North Americans (those with the independent mode of being) than for Asians (those with the interdependent mode of being).

Symbolic Self-Inflation

Is the self perceived to be literally bigger than others by persons with the independent mode of being? Moreover, is such size asymmetry less common and possibly reversed for those with the interdependent mode of being? In our recent work (Duffy, Uchida, & Kitayama, 2004) we asked both American and Japanese respon-

dents to draw a network of their friends by using circles for both the self and friends, and connecting the circles with arrows. One of the dependent variables is particularly relevant for our present purposes. We simply measured the diameter of the circles. For all of our American respondents, the self circle was bigger than the average size of the circles used to designate friends. But this was the case for only 41% of our Japanese respondents.

Further evidence for a cultural divergence in representation of self versus social others occurred in a different measure concerning popularity ratings. After participants completed their sociogram, they were asked to rate on a 0- to 10-point scale their perception of the popularity of each member of the network, including the self. Notice that this method avoids the problem, noted earlier, of using abstract terms such as *average* or *typical* other. Duffy et al. (2004) compared the average rating for all the others against participants' rating of the self's popularity. Whereas 77% of North Americans rated themselves as more popular than the average of the individual ratings for their friends, only 16% of Japanese participants did so, suggesting a significant cultural difference in subjective assessments of self versus other within the domain of popularity assessment.

Self-Uniqueness

Those with the independent mode of being not only seek a positive and somewhat inflated evaluation of the self but also they strive for uniqueness. Within independent cultures such as the United States, whereas expressing unique features of the self often signifies one's freedom and autonomy, within interdependent cultures such as Japan and Korea, doing so is usually perceived as infringing upon the ever-important value of social harmony. In agreement with this analysis, Kim and Markus (1999) have shown cross-culturally divergent preferences for uniqueness. These researchers asked Asian Americans and European Americans to choose one pen from a group of five pens as a gift for completion of a questionnaire. There were two colors of pens. In one condition, only one pen was one color (minority pen), whereas the remaining four were the same color (majority pens); in the other condition, two pens were the same color (minority pens), and the remaining three were another color (majority pens). As predicted, European

Americans in both conditions chose a minority pen more frequently (over 70%) than majority pens, whereas Asian Americans chose a majority pen more frequently than they chose minority pens (under 31%). Hence, European Americans were far more likely than Asian Americans to pursue their self-uniqueness.

Cognitive Elaboration

One cognitive task that is suitable in testing the relative salience or richness of two concepts uses a simple judgment of similarity. It has been established that perceived similarity is greater when a relatively impoverished concept, with a small number of features, is compared to a relatively rich concept, with a greater number of features, than the latter is compared to the former. For example, North Korea is typically perceived to be more similar to the former Soviet Union, because what little is known about North Korea (e.g., communist country, dictatorship, relatively low standard of living, etc.) is very much shared by the Soviet Union. But the Soviet Union by no means seems similar to North Korea, because people usually have substantially more knowledge that is unique to the Soviet Union. Applying this principle, it is possible to assess the relative salience or richness of knowledge about self and social others. Kitayama, Markus, and Kato (1989, reported in Markus & Kitayama, 1991) did this by comparing white American students with American students with an Indian cultural heritage. Replicating numerous studies conducted in North America, Kitayama et al. (1989) observed that Americans judged their friends to be less similar to themselves than they were to their friends. This suggests that for these respondents, knowledge is richer and more salient for the self than for friends. In contrast, this pattern of asymmetry in self-other similarity judgment was reversed for the Indian respondents. Thus, as predicted, for Indians, knowledge about social others is more salient or richer than knowledge about the self.

In describing one's interpersonal actions, people commonly refer to both their own action (what they did) and characteristics of the person to which the action was directed (what this person was like). Within this general scheme, the relative salience of the two types of knowledge may vary across cultures. To investigate this possibility, Kitayama, Uchida, and colleagues (2006) asked both Americans and

Japanese participants to remember an episode wherein they did something to their acquaintance who was either happy or in distress. The main dependent variation was the number of words devoted to the description of the action and the description of the other person. As predicted, Americans used substantially more words to describe the self's own action than to describe the features of the other person, but the Japanese showed a significantly reversed pattern.

Reciprocity Monitoring

If Asians value and elaborate on social relations, they might monitor reciprocal exchanges of support. As Miller and Bersoff (1994) argued, such monitoring enables Asians to return favors to others. To see whether Asians in fact closely monitor reciprocity among their friends, Kitayama, Uchida, and colleagues (2006) invited many pairs of friends to come to the lab. Mutual friends in each pair were then separated into different rooms and asked to indicate for each of many supportive acts how much support they gave to the other and how much support they received from the other. Across three independent samples of Japanese friends, Kitayama and colleagues found that one's perception of the receipt of support and the other's perception about the provision of support were highly calibrated, with a Pearson's correlation of approximately .5. In contrast, among samples of American friends, the modal correlation was zero, showing no calibration at all of reciprocal exchange of support.

Cognition

The third component of the mode of being relates to ways in which people perceive and construe the meanings of attendant situations. On the one hand, self-directed individuals tend to focus attention on one goal-relevant object at a time. The tendency to attend to focal objects at the expense of the field, and using categories, rules, and formal logic in reasoning and judgment, is called "analytic mode of thought" (Nisbett et al., 2001). On the other hand, individuals who are responsive to social contingencies tend to disperse attention to many elements available in the environment. The tendency to attend to many objects and events simultaneously, and to arrive at an understand-

ing of an encompassing event as a whole is called the "holistic mode of thought." These two divergent "systems of thought" are likely to have a number of consequences upon both relatively low-level processing of attention and perception, and relatively high-level processing of reasoning and categorization (see Norenzayan et al., Chapter 23, this volume, for a detailed review).

Attention and Perception

Several recent studies have begun to explore how cultural modes of being mediate basic attention processes (Ji, Peng, & Nisbett, 2000; Nisbett & Masuda, 2003; Kitayama & Duffy, 2004). The central idea of this literature is that what one notices about the external world determines the information available for perceptual and cognitive processing. Early socialization processes and continued engagement in cultural practices shape the aspects or elements of the world to which individuals attend (Chavajay & Rogoff, 1999). So whereas North Americans focus their attention on focal objects and their intrinsic features, Asians tend to disperse their attention more broadly among objects and their contexts.

A variety of findings are consistent with the hypothesized cultural difference in attention (e.g., Masuda & Nisbett, 2001). For instance, Masuda and Nisbett (2001) showed animated underwater vignettes to Japanese and American participants, and asked them to report what they saw. American participants tended first to describe the most salient objects in the scene. Japanese participants were much more likely to begin by describing the background or field. Japanese reported a total of 60% more background or field objects than did Americans. The cross-cultural attention difference has been observed even when very abstract geometric stimuli are used. Kitayama, Duffy, Kawamura, and Larsen (2003) developed what they call the Framed Line Test (FLT) to test cultural differences in attention. In the FLT, participants were shown a line in a square frame and asked to draw a line of either the same absolute length or relative length in another square frame that differed in size. Whereas the absolute task requires ignoring the square frames and focusing attention on the target line, the relative task requires one to incorporate information about the frame into the estimate of the original line by dispersing attention to the sur-

rounding frames. In support of the hypothesis that Americans exhibit a focused strategy of attention, their performance on the absolute task was more accurate than performance in the relative task. Moreover, in support of the notion that the Japanese exhibit a dispersed attention strategy, they were more accurate in the relative task than in the absolute task.

It is noteworthy that analogous effects of attention have been shown for perceptual judgments, with Asians sampling information more widely from context than do Americans (Kitayama & Duffy, 2004). Such attentional differences are likely to be automatic. Thus, Ishii et al. (2003) used a Stroop interference procedure to demonstrate that whereas American's attention is automatically captured by focal verbal meanings in speech comprehension, Asian's (Japanese and Filipinos) attention spontaneously goes more to contextual vocal tones. More recently, the comparable cultural difference has been observed at the level of rapid eye movements. Chua, Boland, and Nisbett (2005) presented both Asian and Caucasian American participants with a large object (e.g., airplane) and its context (e.g., sky with clouds and many buildings in distance). Participants were simply asked to report their picture preferences. Caucasian Americans were much more likely to fixate their eyes on the central object. Asian Americans tended to show many rapid eye movements to contextual stimulus elements. Given the differences in eye movements, it is very likely that cultural differences exist from the very beginning of information processing, even when people are exposed to a seemingly identical stimulus configuration.

As might be expected from this recent series of studies that implicate lower-level cognitions, the brains of Asians and Americans appear to be activated very differently. Using functional magnetic resonance imaging (fMRI) scans, Ketay, Hedden, Aron, Markus, and Gabrieli (2006) observed that Asian Americans show greater conflict when making absolute judgments in the FLT, whereas Caucasian Americans show greater conflict when making relative judgments. Another noteworthy finding comes from a recent study by Gutches, Welsh, Boduroglu, and Park (in press). Their use of stimulus materials similar to those of Masuda and Nisbett (2001), revealed that Americans showed more activation in object processing regions (in particular, the left lateral middle temporal cortex) than did East Asians when studying complex pictures. They also found

that East Asians showed more activation of a background processing area (the left fusiform gyrus).

Reasoning and Categorization

Nisbett and colleagues (2001) have argued that the independent mode of being encourages argumentation, reliance on explicit rules, and the general art of rhetoric that was supposedly invented by Greeks to settle disputes, whereas the independent mode of being fosters more relational epistemology and dialectic ways of reasoning that lend themselves to social harmony (see Nisbett, 2003; Norenzayan et al., Chapter 23, this volume, for reviews). For example, Norenzayan, Smith, Kim, and Nisbett (2002) asked both North Americans and Asians to judge whether an object belonged to one of two categories. One of the categories was defined by dint of an explicit rule, and the other was defined by means of family resemblance. The researchers found that North Americans relied on explicit rules, but Asians tended to base their judgment on family resemblances. A similar point has been made in a classic study by Chiu (1972), and in its more recent extensions by Ji, Zhang, and Nisbett (2004).

Evidence suggests that independent people tend to emphasize logical approaches to problem solving, whereas interdependent people tend to use dialectical approaches. We believe that this difference derives from the social orientation of the respective groups of people toward either confrontation or social harmony: Logical argument is useful in settling disagreement, but dialectic reasoning is more useful in moderating or preempting disagreement. For example, when presented with apparently contradictory propositions, Americans tended to reject one in favor of the other, and even to increase their belief in the more plausible proposition when they saw it contradicted by a less plausible one (Peng & Nisbett, 1999). This "hyperlogical" pattern contrasts with the behavior of the Chinese participants, who tended to find both propositions plausible. Peng and Nisbett also found that Chinese participants showed greater appreciation of proverbs expressing contradictions than did American participants, and Chinese participants were more inclined to "split the difference" in social or intrapersonal conflicts, rather than insisting that one side or the other had to be right. Finally, they found that Chinese participants were more impressed with arguments that re-

flected multiple points of view than were Americans.

Summary

When wide-angle comparisons are drawn between North American and Asian cultures, there often arise a number of intriguing psychological differences. They can be readily classified into three sets, namely, style of action, self–other representations, and cognition. As shown in Figure 6.2, the independent mode of being is associated with the style of action as influence, self-centricity, and the analytic mode of cognition. In contrast, the interdependent mode of being is associated with the style of action as adjustment, other-centricity, and the holistic mode of cognition. One weakness of this literature stems from the fact that most of the reviewed studies are based on college student samples. Yet theoretically comparable findings have been observed among young children (e.g., Fernald & Morikawa, 1993), in community samples (Markus et al., 2004), and in a variety of cultural artifacts (e.g., Kim & Markus, 1999). This literature presents a reasonably strong case for the fundamental role that culture plays in the construction of the self as a mode of being.

DEVELOPMENTAL AND SOCIAL ANTECEDENTS

So far, we have discussed how social relational differences (*gesellschaft* and *gemeinschaft*) might be associated with two contrasting modes of being (independent and interdependent). Moreover, we provided evidence for this analysis by reviewing an emerging body of cross-cultural studies focused on style of action, self–other representation, and mode of thought. So far, however, this evidence leaves open a number of significant questions about the development and antecedents of the two modes of being. In this third section of the chapter, we examine some initial efforts to address these issues. We start with a review of recent theoretical analyses of socialization of independence and interdependence.

Socialization of the Mode of Being

The mode of being is a social product, fostered and shaped through socialization. Recent theoretical advancements on cultural socialization suggest that the independent mode of being is

fostered by socialization practices that encourage autonomy, whereas the interdependent mode of being is promoted by those that encourage symbiotic relations.

Culture and Developmental Pathways

In their discussion on culturally variable pathways of development, Greenfield and colleagues (2003) proposed that the development of the self is contingent upon successfully resolving three universal tasks of human development: relationship formation in infancy, knowledge formation during childhood, and the balance between autonomy and relatedness in adolescence and early adulthood. Yet cultures vary along three important dimensions that mediate the strategies and, ultimately, the trajectories by which individuals resolve these important tasks. First, cultures vary in practices, such as the manner in which parents interact with their children. Second, cultures vary in ecological conditions, such as the size of families or how many people sleep together in the same room. Finally, cultures vary in meaning systems and beliefs regarding the normative and proscriptive beliefs, behaviors, action tendencies, and developmental trajectories. Each of these factors plays an important role in guiding an individual's growth along a pathway toward either independence or interdependence. In terms of relationship formation, which is most relevant to our discussion, Greenfield and colleagues point out that interdependent cultures promote the development of a symbiotic relationship between mother and child, whereas independent cultures foster children's individual autonomy.

The same theme is echoed by another important model by Rothbaum and his colleagues (2000), which proposes that in interdependent cultures such as Japan, the pathway through development is one of symbiotic harmony, whereas in independent cultures, the path is one of generative tension. More specifically, the path of symbiotic harmony entails unity in infancy, in which the distinction between mother and child is blurred, focusing on the other's expectations during childhood, maintaining stable relationships among family members during adolescence, and unconditional loyalty to partners in adulthood. The cultural practices and shared meanings along the pathway of symbiotic harmony foster allocentric attention to relationships, particularly among the kinship network, thereby promoting an interde-

pendent mode of being. In contrast, the path of generative tension emphasizes a constructive role that interpersonal conflict plays in fostering developmental change. Along this path, infant autonomy is emphasized and actively promoted; children are expected to exhibit personal preferences and respect the preferences of others; and the transformation of affiliation from family to peers is expected and promoted during childhood. Moreover, adult relationships are based upon trust individuals confer on each other, rather than on assurance provided by formal and informed social sanctions.

Cultural Differences in Parental Practices

A variety of practices guide children toward different developmental goals. For instance, in many interdependent cultures such as India and Japan, parents co-sleep with their infants and young children, whereas in the independent cultures such as Germany and the United States, most infants sleep in separate rooms (Shweder, 2003). These practices are enforced by relevant cultural beliefs. Needless to say, a variety of ecological conditions can influence sleeping arrangements. For instance, separate sleeping arrangements may not be possible for families living in a one-room adobe hut. Yet, Shweder and colleagues (1997) found evidence that cultural preferences for different sleeping arrangements persist even when such ecological constraints are minimal.

Several studies have focused on Japan and examined cross-cultural variation in mother-infant interaction. In one of these studies, Bornstein et al. (1992) observed contents of maternal speech to infants and found marked cross-cultural differences in the frequencies of affect-salient (e.g., "The ball makes you happy!") versus information-salient maternal speech (e.g., "The ball is red!"). Japanese mothers produced more affect-salient speech, whereas U.S. mothers exhibited speech that was more information-salient and asked information-seeking questions. Similarly, Fernald and Morikawa (1993) found that, compared with their American counterparts, infant directed speech of Japanese mothers contains fewer words but a greater number of affect-salient, nonverbal vocalizations. In terms of nonverbal linguistic behavior, Bornstein et al. (1992) found that Japanese mothers are more responsive than American or French

mothers to infant's social looking. Furthermore, Japanese mothers direct infants' attention to the mother, and specifically to emotional facial expressions, whereas American mothers direct infants' attention to objects and events in the environment (Bornstein, Toda, Azuma, Tamis-LeMonda, & Ogino, 1990).

Further evidence for the cross-cultural variation in socialization practice comes from a well-replicated finding that Japanese mothers tend to exhibit greater symbiotic proximity than American mothers, spending more time in direct physical contact with their infants (see Barratt, 1993, for a review). For example, infants in Japan receive nonmaternal caregiving for about 2 hours a week, whereas American infants receive, on average, 23 hours. As might be expected, Japanese babies show a higher degree of anxiety than do American babies when separated from the mother in the Strange Situation paradigm (Miyake, Chen, & Campos, 1985). Secure and avoidant attachment styles are correspondingly less frequent in Japan. Similar cross-cultural differences persist throughout the toddler period (Zahn-Waxler, Friedman, Cole, & Mizuta, 1996). Taken as a whole, the evidence consistently suggests a systematic cultural bias in socialization practices, with Western mothers distancing the child as a little adult and directing the child's attention to his or her goal-relevant object, and Japanese mothers treating the child literally as a child, and engaging the child in an intimate symbiotic relationship.

Some more recent studies have examined cultures other than the United States and Japan. Drawing on previous evidence that mothers in interdependent cultures exhibit symbiotic or proximate parenting behaviors (which emphasize body contact and body stimulation between the caregiver and child), whereas parents in independent cultures exhibit distal behaviors (which promote face-to-face contact and object stimulation), Keller et al. (2004) proposed that whereas proximate behaviors foster an orientation toward interpersonal relatedness, distal practices create an orientation toward autonomy. To test this possibility, Keller et al. measured both proximate and distal parenting practices of mothers when their children were 3 months of age and explored behavioral consequences for the children at 18 months. The maternal styles (proximate vs. distal) were determined by a systematic coding of a 3-hour

naturalistic observation. Of importance, Keller and colleagues tested an independent, urban, middle-class culture (Greeks); an interdependent, urban, middle-class culture (Costa Ricans); and an interdependent, rural farming culture (Cameroonian Nso). At 18 months, the toddlers' self-recognition (an index of independence) and compliance (an index of interdependence) were measured. Keller et al. found that children of the proximate-style Cameroonian mothers exhibited greater compliance behaviors, whereas the children of the distal-style Greek mothers exhibited greater self-recognition at 18 months. The Costa Rican mothers and children fell between these two groups. These findings support the hypothesis that cultural variations in modes of being begin to emerge at an early point in development; moreover, specific socialization practices play a significant role in this developmental change.

Voluntary Settlement

One source of within-culture variability that has received research attention of late is voluntary settlement. Cultural groups differ greatly in the degree to which they are sedentary or socially mobile. Some individuals emigrate with great effort and determination for a variety of reasons, whereas others decide to stay in the communities of their origin, under seemingly identical circumstances. Cultures may subsequently differ substantially as result of such emigration or the absence thereof. This consideration is especially important in understanding American individualism.

In the last 400 years, the United States has been a major magnet of for immigrants from all over the world. Except for African Americans who were forced to work as slaves, the vast majority of immigrants voluntarily settled in North America. Over nearly three centuries, from the 16th through the 19th century, new lands of the West were continuously exploited and settled by Americans of mostly European descent, with the frontier steadily moved westward. Does the voluntary settlement in a frontier promote an independent mode of being? A number of theorists have suggested an affirmative answer to this question (Bellah et al., 1985; Hochschild, 1995; Schlesinger, 1986; de Tocqueville, 1835/1969; Turner, 1920).

Drawing on this literature, Kitayama, Ishii, Imada, Takemura, and Ramaswamy (2006) proposed that voluntary settlement in a fron-

tier foster independent agency by three mechanisms. First, the initial move toward settlement in new lands of freedom and opportunity requires a strong desire for independence, freedom, and economic prosperity. Hence, there may be considerable self-selection, such that settlers may be more independently disposed from the beginning. Second, frontier life is often harsh, thereby reinforcing the ethos of independence and self-directedness. Third, this ethos is institutionalized, so that the culture of independence is passed on over generations, even when the frontier no longer exists.

According to this hypothesis, there should be elements of the independent mode of being even outside of North America as long as there is a relatively recent history of economically motivated voluntary settlement. Kitayama, Ishii, and colleagues (2006) thus examined Hokkaido—a northern island of Japan—as a natural experiment for testing the voluntary settlement hypothesis. This island had been intensively settled since the 1870s over several decades, primarily by jobless samurais and, subsequently, by farmers. The motivation for the settlement was personal success and achievement in certain tangible terms. The dictum “Boys be ambitious!” broadly attributed to an American educator, Dr. William S. Clark, who served as the first vice-president of the Hokkaido University between 1876 and 1877, eloquently expresses the regional ethos of Hokkaido around that time, which supposedly has since been deeply ingrained into the regional culture.

Kitayama, Ishii, and colleagues (2006) tested three indicators of independent agency, namely, the fundamental attribution error, happiness as personal achievement, and personal dissonance. The results were quite clear: Japanese who were born and raised up in Hokkaido were more similar to Americans than to non-Hokkaido Japanese. Unlike the non-Hokkaido Japanese, the Hokkaido Japanese exhibited the fundamental attribution error. Moreover, unlike happiness for the non-Hokkaido Japanese, happiness for the Hokkaido Japanese was distinctly more personal and grounded in achievement. Finally, the Hokkaido Japanese also showed evidence of personal dissonance, which is motivated by concerns for private self-images. This Hokkaido finding on dissonance is in sharp contrast with typical findings for non-Hokkaido Japanese (Hoshino-Browne et al., 2005; Kitayama et al., 2004), in which the dissonance effect is obtained only in the pres-

ence of certain social cues or contexts that evoke public self-image concerns.

Social Class

Cultural differences that have been demonstrated are often substantial. In terms of effect size, these differences are often in the range of “moderate” to “strong” effect. For example, Miyamoto, Kitayama, and Talhelm (2006) reviewed a large number of published studies on culture and cognition, and found that the mean effect size for the West–East difference, as indicated by Cohen’s d , is approximately 0.70. It goes without saying, however, that substantial individual differences are also present within each of the compared cultures. Although some of these differences are due to a variety of noises in measurement, others are likely to be more systematic. One important variable that describes such within-culture differences is social class.

“Social class” refers to a dimension defined by several, loosely correlated, value-ridden features of one’s position in a society, such as education, ownership, control over the means of production, income, and associated status and prestige. Because these features are value-ridden, some positions are higher than others, resulting in a hierarchy of power, wealth, and prestige. Although some societies are highly hierarchical (e.g., India) and others are relatively egalitarian (e.g., The Netherlands), virtually all contemporary societies have some degree of such stratification (Schooler, Chapter 15, this volume). In recent years, it has become increasingly clear that different social classes foster a variety of different psychological propensities and characteristics.

Snibbe and Markus (2005) focused on one critical dimension of social class (i.e., educational attainment) and argued that college-educated and high-school-educated Americans are characterized by somewhat different models of self and agency. Whereas members of the college-educated group ground their selves in free choice and attainment of personal autonomy, the high school-educated group members emphasize protecting their integrity against adversities of the surrounding world. To examine this analysis, these researchers performed a content analysis on the various kinds of music most commonly preferred by individuals with a high school education (country music) compared to that preferred by college-educated in-

dividuals (rock music). They found that country music lyrics contain themes expressing individual integrity, self-adjustment, and resisting influence, whereas rock music lyrics express individual uniqueness, control over the environment, and influence. Snibbe and Markus provide further evidence by using the free-choice dissonance paradigm. Recall that in this paradigm participants are given a choice between two equally attractive items. Typically, Americans shift their preference for a chosen item upward, while shifting their preference for a rejected item downward. Snibbe and Markus found that this typical American pattern was found for college-educated Americans, but for the high school-educated group, only the downward shift of preference for the rejected item was observed. This finding is consistent with the overall hypothesis that working-class individuals seek to protect their integrity by justifying what they have to give up.

Another important insight into the effect of social class on identity, self, and cognition comes from a series of studies by Schooler and colleagues, who have hypothesized that individuals in positions of higher social status—those in control of the means of production—exhibit aspects of individuality, such as occupational self-direction, intrinsic motivation, and analytic modes of cognition, to a greater extent than individuals with lower social status. Schooler and colleagues link these differences to structural aspects of common working conditions among those with high- or low-status jobs. High-status jobs generally demand greater cognitive flexibility, self-directed action, and independent value orientations. Alternatively, low-status jobs generally promote interdependent thinking (e.g., teamwork), involve little self-directed action, and generally tend to involve routine actions that are part of larger processes (i.e., piecemeal work on an assembly line). Furthermore, these findings are not limited to American social structures: Schooler’s general findings have been replicated in a variety of different cultural contexts, such as Poland and Japan (Kohn, Naoi, Schoenbach, Schooler, & Slomczynski, 1990; Naoi & Schooler, 1985). Additionally, Schooler and his colleagues found that differences in social status are related to child-rearing behaviors, with parents of high social status more likely than low-status parents to promote values of intellectual flexibility, self-direction, and motivation (Kohn, et al., 1990). At present, it is not

clear whether self-direction, arguably associated with middle-class environments, nurtures general cognitive competences (e.g., IQ), analytic skills (e.g., focusing [vis-à-vis holistic] strategy of attention), or both. It is highly desirable to use cognitive tasks such as FLT that dissociate analytic versus holistic cognitive competencies from general cognitive competence.

Taken together, these studies suggest that social status may have an important role in shaping orientations toward the interdependent and independent dimensions of cultural modes of being. At present, it is not known whether working-class Americans are “less independent” than middle-class Americans in all three facets of independence and interdependence we have posited. Snibbe and Markus (2005) have argued that both groups are equally independent, but the specific way in which they are independent varies. Thus, whereas middle-class culture emphasizes self-reliance and self-directedness, working-class culture puts a premium on the protection of integrity. It is also possible that social classes differ in specific profiles of independence defined by the three facets. For example, Americans might have an equally strong tendency to take a style of action as influence, but their mode of thought might be dependent more on their educational attainment, with college-educated groups being much more analytical than high school-educated groups. This and other, related issues must be addressed in future work.

Cultural Affordances

Kitayama and colleagues have defined “cultural affordances” as the potential of cultural environments to evoke different sets of cognitive, emotional, and motivational responses (Kitayama & Markus, 1999; Kitayama, Mesquita, & Karasawa, 2006; see also Gibson, 1979). Cultural affordances result from a biased pool of symbolic resources of culture that are brought to bear on the construction of concrete daily situations (Kitayama et al., 1997; Morling et al., 2002). These symbolic resources are used to define general classes of events and episodes available in a given cultural context (school, exam, business, success, failure, etc.). But more importantly, they profoundly influence more subtle, yet powerful nuances and psychological meanings (pride, shame, obligation, honor, etc.) that are added to the lived experience of such events and episodes. These meanings may often

be highly idiosyncratic and hardly predictable in any specific instances, yet because they are derived or fostered by a pool of symbolic resources available in a given culture, they may be systematically biased over many situations and episodes in accordance with the specific, historically crafted and accumulated contents of this pool. In this way, individual experiences may be collectively constructed through sociohistorical processes (Kitayama & Markus, 1999; Kitayama et al., 1997).

For example, “getting an A in an important course” is likely to be both positive and disengaging (causing one to feel proud) in all cultures. Nevertheless, certain engaging themes, icons, and ideas, such as smiling faces of parents who are very happy to know their daughter’s performance in the course, may be more available in interdependent than in independent cultural contexts. If so, a subtle, yet distinctly engaging element or nuance may be added to the experience for those in the interdependent contexts, but such an addition of engaging nuances may be relatively unlikely for those in the independent contexts. This example illustrates how subtle the effect of cultural affordances can sometimes be. It also suggests, however, that such a subtle effect can be very powerful over time, because it is highly recurrent, present all the time, insofar as all individuals must necessarily be drawing on the pool of symbolic resources of their own culture.

Likewise, it is a common experience among many Asian sojourners in the United States to find that many of their American friends are very nice, complimenting and praising them, but they also feel the compliments and praise to be somewhat excessive. This would have been surely embarrassing in their native (Asian) contexts! After a while, however, the sojourners are resocialized in the United States; that is, they get used to the American-style friendship and, as a consequence, no longer feel their American friends’ praise and compliments are unnecessarily positive, but instead will feel natural and even appropriate. Not surprisingly, Asians’ self-esteem substantially goes up after some period of resocialization in North America (Heine et al., 1999). These examples illustrate that culture is not inert or passive. To the contrary, it often is an active element of psychological experience. The notion of cultural affordances highlights this potentially powerful role of culture’s practices and meanings to

guide psychological processes in subtle, yet highly systematic fashion.

Situation Sampling

It is reasonable that North American cultural contexts have historically incorporated a variety of cultural resources (meanings and practices) that encourage independence of the self; moreover, through enculturation, individuals become capable of recognizing and attuning themselves to the culture's affordances. Thus, Kitayama et al. (1997) proposed that "psychological tendencies . . . are importantly afforded and sustained by the ways in which the attendant social realities are collectively constructed in each cultural context" (p. 1246). It would follow, then, that North Americans and Asians should be most independent and interdependent, respectively, when exposed to social situations that are most routinely available in their own cultural contexts.

Kitayama and colleagues (1997; Morling et al., 2002) explored some implications of this collective construction theory in a series of Japan–U.S. comparison studies that use a situation-sampling method. In this method, situations that meet a certain criterion are randomly sampled according to two different cultural contexts. The situations sampled from the two cultures are then presented to respondents from both cultures. Respondents are then asked to imagine that they are in each of the situations and to estimate their own psychological responses in the situation. With this method, Kitayama and colleagues (1997) discovered that Americans feel more efficacious and esteemed (and therefore independent) when exposed to situations that are most commonly available in their own cultural contexts. In contrast, Asians are especially likely to be self-effacing when exposed to their own cultural situations.

Although Kitayama and colleagues (1997) focused on situational definitions as the primary locus in which each culture's symbolic resources play their role in shaping psychological tendencies of those engaging in the culture, it is also clear that there are many other types of cultural affordances. Indeed, the cultural affordances hypothesis amounts to the idea that culture "primes" different emotion themes (Oyserman & Lee, Chapter 10, this volume). We now turn to this literature. As will be seen, the priming research may fruitfully expand its

scope to examine the entire pool of icons, lay theories, and other symbolic resources that are unevenly distributed across different cultural contexts.

Language, Cultural Icons, Ecology

First, linguistic practices serve as a powerful affordance for certain psychological processes. One case in point comes from an observation that whereas in most West European languages, including English, subject and object are obligatory in grammatically constructed sentences, they are not in most of the remaining languages in the world (Kashima & Kashima, 2003). This phenomenon is called "pronoun drop." Thus, whereas English speakers always remind the listeners that it is "I" who thinks, feels, and so forth, Asian speakers more often than not leave this aspect to the listeners' inferences. Thus, especially in Asian contexts, it is quite informative if the speaker uses pronouns even where they are reasonably inferable from context and thus ordinarily omitted. Kakuno and Ura (2002), who replicated other, related findings (e.g., Masuda & Kitayama, 2004; Miyamoto & Kitayama, 2002), showed that when asked to infer the real attitude of someone who was allegedly requested by an external authority to make a speech on a controversial political issue, Japanese subjects did not infer the attitude to closely correspond to the speech content. Although this finding may be expected to be typical in Japanese contexts, it in fact was observed only when the form of the speech allegedly made by the speaker conformed to the linguistic convention of pronoun drop. When all pronouns (especially *Is*) were inserted, Japanese participants exhibited a quite strong bias to infer that the speaker's real attitude closely corresponded to the speech content.

A second type of cultural affordance has received considerable research attention of late—a variety of cultural icons. For example, the Statue of Liberty, a football stadium packed with enthusiastic fans, Marilyn Monroe, and the like, are some of the U.S. icons, whereas dragons, Great Walls, Mao, and the like, are comparable icons in China. The respective sets of icons may induce the corresponding psychological tendencies for those who are familiar with the two cultures. In many cases, except perhaps for the Statue of Liberty relative to independence, there is nothing inherently either independent or interdependent about these

icons (Why does Marilyn represent more independence than Mao?). Yet American icons such as Marilyn Monroe are associated with independence by virtue of associative connections between America and individualism. Conversely, Chinese icons such as dragons and Mao can prime interdependence by virtue of the associative links between China and collectivistic or interdependent cultural values. The best evidence so far for this possibility comes from a series of studies that examined Hong Kong Chinese, who were expected to be equally knowledgeable about both Chinese and American culture (Hong, Wan, No, Chiu, Chapter 13, this volume). These researchers have demonstrated that the fundamental attribution error, which is more typical in American contexts, can be found even for Chinese, but only if they are exposed to American icons just before they work on the attribution task.

Third, importantly, mounting evidence indicates that some aspects of the two modes of being can be activated when the corresponding ideas or linguistic symbols of independence and interdependence are primed. In one study of this effect, Trafimow, Triandis, and Goto (1991) had American participants read either an individualistic or a collectivistic story. When asked to describe themselves in a seemingly separate study, the participants generated more individual traits in the individualistic story condition, and more group memberships in the collectivistic story condition. In another, similar attempt, Brewer and Gardner (1996) presented to American participants a story written with a number of either singular or plural first-person pronouns (*I, my, me* vs. *we, our, us*). Participants were asked to circle all the pronouns. When asked to judge themselves, the participants in the “I” condition proved to be more independent or less interdependent than their counterparts in the “we” condition. These findings have recently been extended to some cognitive effects, with more analytic or less holistic tendencies manifest after the “I” priming than after the “we” priming (e.g., Kuhnen & Oyserman, 2002). Even more intriguing, Gray, Ambady, Ishii, and Kitayama (2006) examined Americans and found that after a subliminal exposure to affiliation-related words (Lakin & Chartrand, 2003), participants become especially sensitive to vocal tone in a vocal Stroop paradigm (Ishii et al., 2003)—a marker feature of interdependence.

It is not clear whether the priming of independence and interdependence is different in kind from the priming effect demonstrated with cultural icons. It is possible that cultural icons are much more tightly embedded in a specific culture’s practices and institutions, and as a consequence, priming effects due to these icons are entirely dependent on immersion in that particular cultural context.

At first glance, this consideration might seem unlikely to apply to the pronoun (*I* vs. *we*) priming effect, because this effect is grounded in the fact that every society has elements of both independence and interdependence. The relative frequency or prevalence of different pronouns may vary across cultures and societies. The story might not be so straightforward, however. If it is really true that the personal self is always defined as embedded in interpersonal contexts in Asia, the representation of the personal self (*I*) might have a greater overlap with the representation of the social or communal self (*we*). If so, the pronoun priming effect might be predicted to be much weaker in interdependent than in independent contexts. This question has yet to be addressed: There is no published work on pronoun priming outside of Western cultural contexts.

A promising way to conceptualize culture, then, is to think about it as a series of priming operations by a great many cultural artifacts, practices, discourses, and institutions, of which the specific priming manipulations examined by psychologists so far are only a few select examples. These and many other priming operations embedded in a culture’s practices and meanings constitute what Kitayama, Mesquita, and Karasawa (2006) have called the “cultural affordances” of a given social setting. As we see later, it is likely that many more cultural artifacts, such as ads and textbooks, do carry images that reinforce rather than compromise the primary values of culture.

Fourth, cultural affordances may also come from cultural ecology. After all, especially in the modern world, there is no purely natural ecology (Watsuji, 1935/1961). Nature itself is already fully cultural because it has been drastically transformed through human interventions (Diamond, 1997). In a recent study, Miyamoto, Nisbett, and Masuda (2006) systematically collected photographs of scenes from several cities of differing size in both Japan and the United States, and examined both subjective and objective characteristics of the

scenes. They found that, compared to their American counterparts, Japanese scenes tended to be more complex, to contain more objects, and to be more chaotic or cognitively confusing. Moreover, they went a step further and argued, using initial empirical evidence, that the relatively complex Japanese scenes may in fact induce relatively holistic cognitive styles. The attention of both American and Japanese participants became more holistic when participants were exposed to a series of scenes from Japan than when exposed to those from the United States.

Public Artifacts

The cultural ethos of independence and interdependence is likely to be incorporated into a variety of cultural artifacts, such as ads, icons, and media materials, which in turn may function as potent cues that prime the culturally sanctioned mode of being (Hong, Morris, Chiu, & Benet-Martinez, 2000). In recent years, there has been a concerted effort to demonstrate systematic cross-cultural differences in public artifacts.

For example, Markus, Uchida, Omoregie, Townsend, and Kitayama (2006) sampled actual media coverage of the 2000 and 2002 Olympics from newspapers, magazines, and television programs in the United States and Japan, and analyzed contents of the coverage, including statements of athletes, reporters, and commentators. In both Japanese and American contexts, Olympic performance was explained mainly in terms of the actions of athletes. Yet, Olympic actions (agency) were illustrated and understood differently by the athletes themselves and the media. In the American context, agency was explained as independent and disjointed (Markus & Kitayama, 2004), separate from the athlete's historical background or social and emotional experience. Rather, performance was mainly explained through positive personal characteristics and features of the competition. In Japanese contexts, however, agency was explained as interdependent or conjointed (Markus & Kitayama, 2004), strongly connected with athletes' backgrounds and others in the interpersonal relationships. For example, for Naoko Takahashi, a Japanese gold medalist in the women's marathon, media coverage almost always mentioned her relationship with her coach. Such differences, which can be seen in explanations of the nature

of intentional agency in the media coverage, have same patterns as the cross-cultural differences, which can be seen in individual behavior or cognition.

Contents of ads also vary systematically across cultures. Kim and Markus (1999) analyzed how the themes of conformity and uniqueness are used in advertisements from various types of magazines (from business to youth/pop culture) in the United States and Korea. As we explained in the previous section, East Asians prefer conformity, whereas North Americans prefer uniqueness in the individual behavioral level. Consistent with that finding, Korean magazine advertisements are more likely to use conformity-related messages or appeals (95%), such as promoting group harmony or following a trend, than uniqueness-related messages (49%). In contrast, American magazine advertisements are more likely to use uniqueness-related messages or appeals (89%), such as emphasizing freedom or choices, than conformity messages (65%). Similarly, Han and Shavitt (1994) pointed out that Korean magazine advertisements use collectivistic appeals much more than do American advertisements, which in turn use individualistic appeals much more than do Korean advertisements.

Yet another example of public artifacts that potentially have the most powerful consequences for the development of culturally divergent modes of being comes from textbook materials (see also McLelland, 1985). In a recent content analysis of elementary school language textbooks in Japan and the United States, Imada (2005) found that the cultural values and beliefs used in the textbooks are significantly different across cultures. She showed that collectivistic values, such as conformity and interdependence, are more likely to be used in the Japanese textbooks than in American textbooks, whereas individualistic values, such as self-direction, achievement, and power, are more likely to be used in the American textbooks than in Japanese textbooks. Moreover, American stories have more pictures that focus only on one person and are more likely to attribute the outcomes to internal factors, such as personal characteristics or effort, than do Japanese textbooks. In contrast, Japanese stories have more pictures with two or three characters and are more likely to attribute the outcomes to external factors, such as other people's behavior or the situation.

CONCLUSIONS

Culture in the Mind

A central thesis of cultural psychology holds that psychological processes in the sense of standardized operational procedures of cognition, emotion, and motivation are socio-culturally afforded; as a consequence, what initially appears to be a fully natural part of the human mind may in fact be saturated with culture (e.g., Bruner, 1990; Cole, 1996; Markus & Kitayama, 1991; Shore, 1996; Shweder, 2003). Only during the last decade or two has this point of view taken a strong hold in the mainstream of psychology and begun to influence other social science disciplines (but see LeVine, Chapter 2, and Triandis, Chapter 3, this volume, for important historical precursors).

In fact, the idea that culture becomes part of the mind was also largely ignored in most of anthropology and sociology, where the main focus was on what Durkheim called “social facts” such as rituals and social institutions (but see LeVine, Chapter 2, this volume, for important exceptions, e.g., Sapir’s elaborate view on the culture–mind interaction). Psychology was largely missing, and in its place were vaguely defined notions of “primitive minds” and “rational agents.” In a way, cultural psychological investigation of the last decade rationalized primitive minds by revealing the coherent logic of them, while socializing the rational agents by specifying the sociocultural affordances for them.

Given the disciplinary history and backgrounds that placed a sharp division between culture and mind, the notion that culture and the psyche make each other up (Shweder, 1991) came as a fresh revelation to many culturally oriented psychologists and psychologically oriented anthropologists and sociologists. With this idea salvaged and returned to the center stage of the study of culture, cross-cultural comparison became something much more than a litmus test of universality.

The hypothesis of mutual constitution implies that the human mind, by its very nature, is designed to be socioculturally shaped and completed. It follows that the human mind is best understood when cast in varying contexts of different cultures and societies. Since the theoretical shift promoted by Shweder and other pioneers during the 1980s and 1990s, cross-cultural comparison has begun to be recog-

nized as an indispensable part of all human psychology. In this emerging perspective, cross-cultural comparison can no longer be dismissed as a pastime for psychologists. To the contrary, it is an indispensable tool for theory building in all areas of human psychology.

In this chapter, we have argued that many of the recent advances in cultural psychology can be integrated by conceptualizing the self not so much as semantic or conceptual structures, but more as a mode of being, or *modus operandi*, that is, a set of standard operating procedures in major psychological functions such as cognition, emotion, and motivation. We traced the origins of the mode of operation to cross-culturally divergent structures of sociality. Moreover, we identified three facets of the mode of being, and argued that these facets are often correlated but can surely be dissociated under certain historical conditions.

Critical Appraisals

The approach to culture, delineated in this chapter, has received some concerted criticisms. In closing this chapter, it would be appropriate to discuss some of these critical appraisals. In particular, two lines of criticism against our approach are worthy comment.

Stereotyping?

First and foremost, independence or interdependence is not a label assigned to a set of psychological traits. It is often argued, however, that “independence” is defined in terms of both certain autonomous, individually oriented behaviors (e.g., choice, social mobility, and self-expression) and corresponding subjective experiences (e.g., sense of autonomy and power), whereas “interdependence” is defined in terms of cooperative and prosocial behaviors (e.g., conformity, compliance, and cooperation), and accompanying subjective experiences (e.g., harmony and trust). This argument leads to a caricature of people who fit either one or the other of these two sets of behaviors. For example, a renowned developmental psychologist recently noted:

The characterization of cultures as individualistic or collectivist . . . is likely to be false, and it serves thereby to stereotype people and groups. . . . The idea [is] patently false for one simple reason: most groups . . . are structured hierarchically . . . and

people in positions of power in those hierarchies are often highly “individualistic.” (Turiel, 2004, p. 92)

We do well to remember that personal autonomy and social relations are both significant elements of human social functions; thus, they are likely to be universally available in all cultural contexts. This means, for example, that practices, such as choice, self-expression, conformity, and cooperation, and subjective experiences, such as harmony and disagreement, are available in all cultures. Nevertheless, it is possible that any one of these practices and experiences is powerfully structured and configured in terms of an underlying model of self as either independent or interdependent. For example, there may be different ways of making a choice that are more amenable either to an independent or to an interdependent model of self (Kitayama et al., 2004). Likewise, although cooperation and trust are available and can easily be found in all cultural contexts, they can also take quite diverse forms depending on the underlying model of self as independent or interdependent (Yamagishi & Yamagishi, 1994). Whereas in the United States trust is grounded in the perceived disposition of another person, in Japan it requires specific interpersonal connections (Brewer & Yuki, Chapter 12, this volume). Cultural models of independence and interdependence provide resources and constraints for handling many universal tasks, such as choice, competition or cooperation, and agreement or disagreement.

Seen from this vantage point, the cultural analysis presented here is entirely consistent with the enormous flexibility and variability of human behaviors and cognitions. This flexibility or variability, however, is made possible by numerous cultural and largely social resources and constraints. The independent or interdependent model supplies one significant set of such social resources and constraints.

Personal Values and Beliefs?

Cultural models of self comprise many practices and public meanings that define the landscape of the cultural environment. Many of the practices and meanings are based on certain values and beliefs. For example, practices based on the Protestant relational ideology

(Sanchez-Burks, 2005) were established on the basis of, and, can be traced back to certain theological ideas of Calvin and other founders of Protestantism. Nevertheless, once established, these practices comprise a collectively constituted environment of capitalism, in which each individual in the society had to survive, and with which each individual had to cope. In this particular case, whether one believes in Protestantism or values any aspects of this theological variety of Christianity would simply be irrelevant. Likewise, a cultural model of the self as interdependent is likely to have established many aspects of a cultural environment, such as communicative practices (e.g., high-context communication), interpersonal routines (e.g., various rules of etiquette), and social institutions (e.g., a company as family). To participate and even to flourish within this collective environment, however, it is not necessary to be aware of the etiology of this environment, much less to endorse personally archaic values or beliefs underlying this environment.

Traditionally, the only means available for psychologists to measure culture was attitudinal questionnaires. Thus, numerous studies were conducted to determine whether Americans are in fact more individualistic and independent, and whether Easterners are more collectivistic and interdependent. Many factors, including acquiescence bias (Schimmack et al., 2005), reference group effect (Heine et al., 2001), and culturally variable referents of abstract concepts (Peng et al., 1997), severely compromise this literature. Thus, without adequate control of these issues, whether statistical or conceptual, the results of these questionnaires can be extremely misleading. Indeed, as noted earlier, one might often get an impression that cross-cultural differences are neither strong nor systematic (Oyserman et al., 2002). From this type of observation, some researchers have immediately jumped to the conclusion that cultural variation in practices and meanings is illusory. For example, a cross-cultural psychologist stated:

The evidence . . . overwhelmingly indicates that the Japanese are not more collectivistic than Americans; if anything, in some cases the Japanese are more individualistic than Americans. Thus, these differences cannot possibly account for differences in self-construals between the two countries. . . . (Matsumoto, 1999, p. 298)

However, once researchers adequately control for certain biasing effects of survey questionnaires (e.g., Heine et al., 2002; Schimmack et al., 2005), cross-cultural variation is quite systematic and sizable even in paper-and-pencil measures of values and beliefs. Moreover, as we have indicated, once behavioral measures are tested, cross-cultural differences that are indicative of the corresponding modes of being are bound to be even more systematic and sizable.

Toward an Implicit Measure of Independence and Interdependence

This said, however, we wish to emphasize that the field will be better served by a renewed effort to develop a more valid measure of independence and interdependence. As we mentioned earlier, to capture individual differences on this dimension, researchers have traditionally relied on several different attitudinal scales (e.g., Singelis, 1994). All these scales probe one's independence or interdependence in terms of explicit self-reports ("In general I make my own decisions" for independence and "When my opinion is in conflict with that of another person's, I often accept the other opinion" for interdependence). In addition to all the artifacts that might compromise the cross-cultural evidence based entirely on this type of measures, there is a lingering suspicion that such explicit measures of self might have an inherent limitation (Kitayama, 2002). This may be the case, because people's behavioral propensities toward independence or interdependence might be embodied, automatized, or spontaneous, and thus largely implicit; that is, they might be rarely self-reflective, deliberate, or even conscious. If there is only a limited conscious access to such behavioral propensities (Nisbett & Wilson, 1977), explicit self-report might be ill-suited as a tool for measuring them.

Many of the studies reviewed in the main body of this chapter used the notion of independent and interdependent self to predict some systematic cross-cultural variations in the pattern of cognitive, emotional, and motivational responses and behaviors. Yet, given the cumulative evidence that was reviewed, we wonder whether the converse of this standard logic might prove to be equally fruitful in future work; that is, it might be possible to use the pattern of, say, emotional responses as a

means for implicit assessment of independence and interdependence.

We recently suggested, for example, that one promising measure is the extent to which engaging or disengaging positive emotions are linked to happiness (Kitayama, Mesquita, & Karasawa, 2006). Furthermore, we may also use the relative intensity of engaging versus disengaging emotions. Individuals may be said to be more independent (or interdependent) if their happiness is predicted more by disengaging positive (or engaging positive) emotions, if they experience disengaging (or engaging) emotions more, or both. Kitayama, Mesquita, and Karasawa (2006) reported initial evidence for the convergent validity of these measures and recommended that future research directly assess the predictive validity of these implicit measures of independence and interdependence with respect to a variety of cross-cultural differences in cognition, such as analytic versus holistic thought (e.g., Nisbett et al., 2001), and motivation, such as self-enhancement and self-improvement (e.g., Heine et al., 1999). To the extent that the self is embodied we suspect that many of the behavioral or online responses of the self might be better predicted by implicit measures of independence and interdependence than by their explicit counterparts, such as the one developed by Singelis (1994).

Future Directions

As we have seen, the extensive empirical studies on culture have revealed a large number of differences. Paradoxically, however, this work has also underscored an equally important set of cross-cultural similarities. Often, the same psychological function is configured or enabled in terms of culturally contingent psychological processes. Having the same psychological function, therefore, does not imply any universal psychological laws. As Richard Shweder (2003) observes, universal principles of psychology may reveal themselves more often in the diversities than in the uniformity of psychological functions. The same theme is echoed in some recent efforts to reunite evolution and culture (Konner, Chapter 4, this volume; Richerson & Boyd, 2005). Future work may therefore focus on culturally contingent solutions for carrying out many universal psychological functions or tasks (Norenzayan & Heine, 2005).

It is also important to reiterate that the work on culture and the self so far has focused

mostly on adult, largely college student populations. Much more developmental work is necessary to understand how members of a cultural group may acquire the culturally contingent ways of being a person. Moreover, there is an increasing need to examine community samples. Another weakness of the field stems from the fact that much evidence so far comes from East–West comparative studies. It is a reasonable research strategy to start with groups of maximal contrast. Yet it should also be kept in mind that much of the existing variation might be masked by this particular approach. Studies on social class, voluntary settlement, and cultural affordances, summarized in this chapter, may represent one extremely important direction for future work that can fruitfully supplement the macroscopic comparisons between large cultural regions such as East and West.

Finally, culture is both inside and outside the mind. As much as psychological processes are shaped by practices and meanings of culture, they do create and perpetuate the public practices and meanings. More detailed studies on practices and meanings—including those pertaining to their origins, changes, accumulation—are very much needed. As we mentioned earlier, some notable beginnings have already been made. Yet a more systematic effort toward theorizing on what Sperber (1996) called the “epidemiology of cultural ideas” is justified, insofar as these ideas eventually constitute or complete the mind of people who engage with them. We predict that much mileage would be gained in the near future by focusing on socialization, regional variation, and related phenomena and processes discussed in this chapter.

In all these future endeavors, it will serve us well to be reminded always of the fundamental insight of G. H. Mead and his contemporaries, who argued that self is a system of (often spontaneous) behavioral regulation that is aligned to the symbolic environment of culture. According to this view, the self is simultaneously symbolic and behavioral, cognitive and emotive, and most of all, grounded in biology, yet constantly shaped by culture. Indeed, this view suggests and reinforces the conceptualization of the self as a cultural mode of being. Just as Mead anticipated nearly a century ago, we believe that, if conceptualized this way, the self will continue to be an indispensable anchor in all analyses of the interface between culture, society, and psychology.

NOTES

1. It is ironic that even what may be called “independent” behavior is strongly enforced by societal norms. In North America, for example, there is a strong moral prescription for personal control and autonomy (Lachman & Weaver, 1998). When perceived as failing to meet this cultural standard, one is strongly stigmatized and prejudiced against (Crandall et al., 2002). Nevertheless, it is possible that norms enforcing interdependence are more explicit than those enforcing independence. The latter may be manifest, as in the example earlier, only when violated; typically, they may stay dormant because they are antithetical to the very quality (i.e., freedom from norms) they try to enforce (Garfinkel, 1967).

2. It is of note that an analogous separation between the personal and the public is found in Confucian cultures such as China, Japan, and Korea (Kitayama & Markus, 1999). Because Calvinism and Confucianism may share a strong achievement orientation, a reasonable conjecture is that a tendency to focus on the focal public domain of work might be one marker of such an orientation. However, it should also be kept in mind that specific meanings and practices associated with the work/public and the social relation/private are very different between the two cultural traditions (e.g., Sanchez-Burks & Lee, Chapter 14, this volume).

CHAPTER 7

Integrating System Approaches to Culture and Personality

The Cultural Cognitive-Affective Processing System

RODOLFO MENDOZA-DENTON
WALTER MISCHEL

O chestnut-tree, great-rooted blossomer,
Are you the leaf, the blossom, or the bole?
O body swayed to music, O brightening glance,
How can we know the dancer from the dance?
—W. B. YEATS, *Among School Children*

As the chapters in this volume attest, the foundational premise that culture and person co-constitute one another, perhaps more than any other, characterizes contemporary cultural psychology (Cole, 1996; Kitayama, 2002; Miller, 1997; 1999; Piker, 1998; Shweder, 1990). Ironically, however, this very premise is most challenging for a cultural psychological view of personality, for “personality” has historically been, and in much cross-cultural research continues to be, conceptualized as the qualities of the individual that are separable from context

(Kitayama & Markus, 1999; Pervin, 1999; Poortinga & Hemert, 2001; Shweder, 1991).

The challenge for a cultural-psychological approach to personality remains to specify the nature of, and the mechanisms underlying, the co-constitution of person and culture. This chapter brings together insights from various theoretical and empirical lines of research (e.g., Hong & Chiu, 2001; Hong, Morris, Chiu, & Benet-Martinez, 2000; Kashima, 2001, 2004; Markus & Kitayama, 1998; Mendoza-Denton, Shoda, Ayduk, & Mischel, 1999; Cohen, 1997)

that together are rising to this challenge and bringing into focus a new paradigm for the study of culture and personality. At the core of this emerging consensus are discoveries over the past 20 years in personality science and social cognition that are remarkably consistent with the premise of cultural psychology. These findings allow us to revise the long-standing assumption that situations, context, and culture are somehow “noise” or “error” that obscures the consistency of personality and obstructs the search for universals. Rather than searching for fundamental human qualities that describe people *in spite of* cultural differences, this approach focuses on the cultural differences *themselves*. Cultural differences in social behavior, in this view, are meaningful manifestations of a dynamic, culturally constituted personality system, the structure and governing principles of which may, indeed, be universal.

THE CULTURE AND PERSONALITY PARADOX

From its inception, a bedrock assumption in personality science has been that people have discernible qualities that supercede contexts and situations (Mischel, 2004; Mischel, Shoda, & Mendoza-Denton, 2002). Within this approach, a person who is high in conscientiousness should be more conscientious than most people in many different kinds of situations, and would do the appropriately conscientious thing as required by his or her culture. By the 1960s, however, it became increasingly clear that the data did not bear out this assumption, with converging data from independent investigators (Hartshorne & May, 1928; Mischel, 1968; Newcomb, 1929; Peterson, 1968; Vernon, 1964) consistently finding only modest evidence for cross-situational consistency of behavior (Mischel, 2003; Shweder, 1991; B. B. Whiting & Whiting, 1975). Bem and Allen (1974) coined the term “personality paradox” to refer to the discrepancy between the lack of strong empirical support for cross-situational consistency and our intuition that stable qualities in fact exist.

Cultural psychologists interested in the relationship between culture and personality are today faced with an analogous dilemma. On the one hand, it has been shown that for many classes of behavior, within-culture variability is greater than between-culture variability

(Barnouw, 1985; Bock, 2000; Inkeles, 1996; Kaplan, 1954; Wallace, 1961; Triandis, 1997; J. W. M. Whiting & Child, 1953; B. B. Whiting & Whiting, 1975). On the other hand, and despite the data, as perceivers and researchers we continue to have a strong intuition that some type of commonality unites the French or the Japanese, and makes them different from Argentines or the Senegalese. How does one reconcile these seemingly opposing positions? The response to the 1960s personality paradox speaks directly to the issues and alternatives faced when dealing with this “culture and personality paradox.”

ONE RESPONSE: UNCOVER TRAITS THROUGH METHODOLOGICAL REFINEMENT

One reaction to the 1960s personality paradox was to assert that the findings on the variability of behavior across diverse situations simply reflect noise and error from inadequate sampling. In this view, the emergence and identification of cross-situational consistency is a matter of methodological improvement, primarily requiring better reliability through denser data sampling (Epstein, 1979), or more precise specification of the people or situations to which traits apply (Bem & Allen, 1974; Epstein & O'Brien, 1985; see Mischel & Peake, 1982, 1983; Snyder & Ickes, 1984; and Shweder, 1991, for lengthier discussions on this topic). Accordingly, no personality paradox in fact exists: One can continue to eliminate the role of situations by aggregating people's behavior across diverse situations, and by using global assessments that exclude context. At its core, then, this approach remains committed to treating situational variability as measurement error.

This response, though greeted with great enthusiasm, has paved the road for a resurgence of culture and personality research that, in spite of its methodological rigor, has not addressed the basic challenges to the paradigm's fundamental assumptions (e.g., Mischel, 1968). The consequence has been to reinforce further the metaphor shared by traditional personality and attribution theories “that construes skin as a special boundary that separates one set of ‘causal forces’ from another. On the sunny side of the epidermis are the external or situational forces that press inward on the per-

son, and on the meaty side are the internal or personal forces that exert pressure outward” (Gilbert & Malone, 1995, p. 21).

Today, a principal impetus in research on culture and personality is devoted to establishing the universality of a personality trait structure, reducible to a discrete number of dimensions. This approach has largely focused on replicating the “Five-Factor Model”—open-mindedness, conscientiousness, extraversion, agreeableness, and neuroticism—across cultures (e.g., McCrae & Allik, 2002), with recent efforts aimed at “mapping” the world across the five dimensions (Allik & McCrae, 2004; McCrae, 2004). The goal of this approach is not so much in finding that the French, for example, are lower on agreeableness than Americans (McCrae, 2004), but rather that both Frenchmen and Americans can be described in terms of the five factors. Proponents of this approach cite evidence from animal studies (e.g., Gosling & John, 1999; Gosling, Kwan, & John, 2003) and heritability studies (Bouchard & Loehlin, 2001; Loehlin, McCrae, Costa, & John, 1998) as evidence for the likely biological basis of trait structure (see Triandis & Suh, 2002). It has been proposed that biological substrates underlie differences in the Big Five and, more recently, that such biological differences cause cultural differences (McCrae, 2004).

The growing literature on global traits and culture has been both ably reviewed (e.g., Triandis & Suh, 2002), and ably critiqued (e.g., Bock, 2000; Kitayama, 2002; Pervin, 1994; Shweder 1991; see also Peng, Nisbett, & Wong, 1997) elsewhere, and is not the focus of this chapter. Nonetheless, we note three important points: (1) Efforts to describe cultures in terms of a common metric assume a context-free psychic unity that cultural-psychological research is finding evidence against (e.g., Heine, Lehman, Markus, & Kitayama, 1999; Iyengar & Lepper, 1999; Norenzayan, Choi, & Peng, Chapter 23, this volume); (2) personality assessments that rely on generalized traits—including indigenously derived ones (e.g., Cheung & Leung, 1998; Church, Katigbak, & Reyes, 1996, 1998)—tacitly accept a definition of “personality” in terms of consistency across both time and situations; and (3) convergent evidence from self- and peer-ratings, or from animal studies, tell us a lot about peoples’ categorization processes (Bock, 2000; Church,

2000; Morris, Nisbett, & Peng, 1995), but only a partial story about the behavioral expressions of the personality system (Borkenau, Riemann, Spinath & Angleitner, 2006; Cervone, 2004; Shoda, 1999). Our focus below is on giving a voice to the rest of that story.

A SECOND RESPONSE: TAKING VARIABILITY SERIOUSLY

To reiterate, the data over the course of a century have shown that cross-situational variability is as at least as impressive as cross-situational consistency (Mischel et al., 2002). Whereas such variability is considered error or noise within traditional approaches, research over the past 20 years has harnessed this variability, with the hunch that a new locus of personality is to be found within this variability. But how can information about behavioral variability across situations, rather than behavioral stability across situations, possibly yield information about dispositions? An analogy from automobiles is helpful (Epstein, 1994). The analogy begins with the recognition that automobiles, like people, are readily grouped in terms of their area of origin. Peugeot, for example, is different from Mitsubishi, which is different from Chrysler. It is helpful to be able to compare these different makes of car according to certain dimensions. Are they gas guzzlers or economical? Are they clunky or speedy? Silent or noisy? Such generalizations are, of course, useful in orienting buyers toward a particular brand, yet only provide distal cues about the *mechanisms* that lead to these differences—about what is going on under the hood (Cervone, 2005).

As beleaguered car owners can attest, when experts ask diagnostic questions about cars, their questions focus on the *conditions* under which certain events occur. The types of questions asked of car owners—*When* does the car make that particular screeching sound? Does the car stall only *when* it’s going uphill?—can give clues to the expert about identifying the source of the surface characteristics (e.g., noisiness) and why the car does what it does. The conclusions drawn about the source of the problem, for example, will be different if the car seems to make noise when trying to accelerate (loose fan belt) as opposed to when trying to shift gears (transmission issue). In a fascinat-

ing way, then, information about how the car behaves in relation to different driving situations can be quite diagnostic about the car itself.

Similarly, identifying the conditions under which an individual displays a given behavior can be critical in understanding personal dispositions—in revealing, as it were, the engine driving the person. That is, even if two individuals display the same overall average level of behavior, depending on the pattern of *where* it is displayed, one may draw drastically different inferences about the person (Kammrath, Mendoza-Denton, & Mischel, 2005; Mendoza-Denton, 1999; Plaks, Shafer, & Shoda, 2003; Shoda & Mischel, 1993). Suppose for example, that Jack so consistently puts work above all else that his friends and family know they cannot count on him for social or family obligations. Jacques, on the other hand, is extremely dependable when it comes to interpersonal obligations, but is consistently late and sloppy when it comes to his nine-to-five job. Even though, on average, both Jack and Jacques might be seen or rated as equally dependable, their distinct patterns—if observed repeatedly and across multiple samples of situations—may be highly informative about differences in their motivations, goals, values—and importantly, their cultural background (Hong & Mallorie, 2004; Mendoza-Denton, Ayduk, Shoda, & Mischel, 1997). More than collections of ever more specific but disjointed behavior-in-context descriptions (see Shweder, 1991), these *if . . . then . . .* (if situation A, then s/he does X, but if situation B, then he or she does Y) profiles—if stable—can yield important clues about the underlying system that generates them.

Evidence for the Stability of *If . . . Then . . .* Profiles

To test for the stability and meaningfulness of *if . . . then . . .* profiles, Shoda, Mischel, and Wright (1994) analyzed the behavior of children over the course of a summer as it unfolded *in vivo* within a summer camp. The children's social behavior (e.g., verbal aggression, withdrawal, prosocial behavior) was unobtrusively observed and recorded as it occurred in relation to various interpersonal situations, with an average of 167 hours of observation per child over the course of the 6-week camp.

Nominal versus Psychological Situations

How did the researchers classify the camp situations into meaningful categories? Situations can be classified at different levels. At one level, one can describe situations *nominally*; in other words, according to their surface features (e.g., study hall, cabin meeting; see B. B. Whiting & Whiting, 1975). Unfortunately, nominal situations often contain a wide array of interpersonal psychological events for different people and different cultural groups. As an example, for one group, being “at the market” may involve quickly finding one's groceries, getting on the shortest checkout line, and leaving the store as soon as possible. For another group, being “at the market” might involve haggling with one's favorite vendor over tea, and socializing with neighbors while choosing fruit. As such, then, situations can also be meaningfully grouped according to their important psychological features, which may cut across nominal situations and settings. Such clusters have been referred to as “psychological situations” (Shoda et al., 1994).

To be able to group the situations in terms of the psychological features that seemed important to the children at the summer camp, Wright and Mischel (1988) asked those who knew the children—the camp counselors as well as the children's peers—to describe them in detail. Specifically, they were asked to imagine that the interviewer was new to the camp and the campers, and to “tell me everything you know about (target) so I will know him as well as you do.” This was followed by standard prompts (e.g., “Anything else?”). This methodology yielded voluminous “thick description” (Geertz, 1973; Shweder, 1991) on the cultural group under study (in this case, the kids at the camp), with the added benefit of stemming from not one but many “cultural experts.” This allowed the researchers to identify those features that the experts agreed were important to the population, rather than being idiosyncratic to any given informant. To find the common themes in these descriptions, responses were coded and subjected to cluster analysis.

Confirming the importance of traits in the language use of Americans (Church, 2000), much of the content of the descriptions consisted of trait terms. However, the data *also* revealed that these trait descriptors tended to be *hedged* spontaneously, that is, described in terms of the *conditions* under which targets displayed particular

qualities (e.g., “Johnny gets aggressive *when* he gets teased about his glasses”). Clustering the types of situational hedges used to describe the targets revealed five psychological situations that seemed important to the kids at the camp: three negative situations (“peer teased, provoked, or threatened,” “adult warned,” and “adult punished”) and two positive situations (“adult praised” and “peer approached prosocially”). The distinction between nominal and psychological situations, though subtle, has important implications, because to the degree that culture dictates the types of situations that “go together,” exercises in the generalizability of nominal situations may be limited in their usefulness (Mendoza-Denton et al., 1997). In terms of assessment, identification of such psychological situations cannot be known without deep familiarity with the culture. We return to this point in the “Implications” section of this chapter.

***If . . . Then . . . Profiles:* Meaningful Patterns of Variability**

Figure 7.1 shows illustrative profiles for two children at the camp. Their verbally aggressive behavior across the five types of psychological situations described earlier (Shoda et al., 1994) is shown in Z-scores—in other words, the children’s observed level of aggression in that situation, in standard deviation units, relative to the mean of the entire sample (Z_0 on the Y axis). Thus, these profiles do not simply reflect the fact that situations, unsurprisingly, make a difference (e.g., on average, people tend to be more aggressive when teased than when praised). The two lines within each panel indicate the profiles based on two separate, nonoverlapping samples of situations, shown as a solid line and a dotted line. It is worth noting here that the fact that these stability coefficients are found when reliability is high (dense data sampling) flatly contradicts the key trait assumption that variability in a person’s behavior across situations is “noise” (see Mischel & Shoda, 1995; Mischel, 2004). In more recent research, the profile similarity in twins has been found to be greater than chance (Borkenau et al., 2006).

The feature of *if . . . then . . .* profiles that is important for this analysis is that they readily invite questions about the person’s construals of different situations, and the relevant motivations, goals, expectations, and processing dynamics. Child 9, for example, reliably becomes

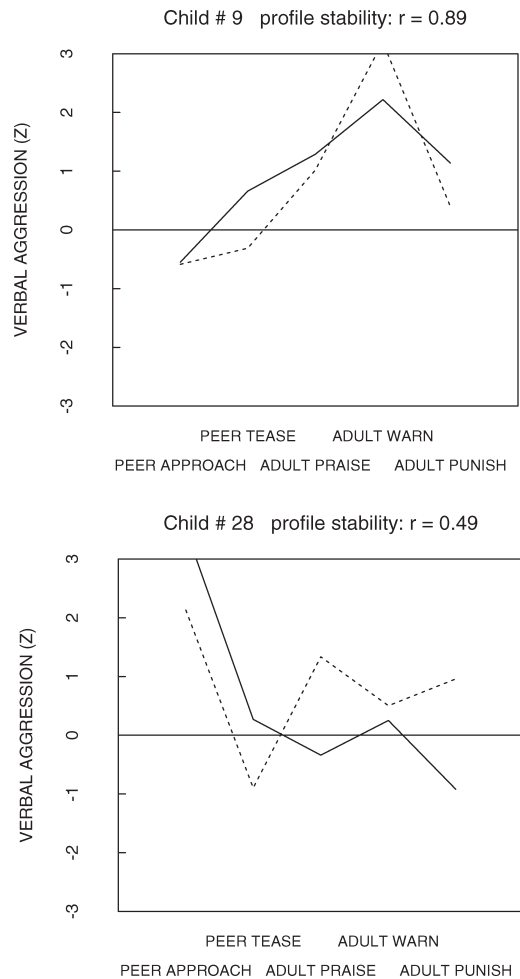

FIGURE 7.1. Illustrative *if . . . then . . .* “signatures” of verbal aggression in relation to five situations in two nonoverlapping time samples (solid and dotted lines). Data are shown in standardized scores (Z) relative to the normative levels of verbal aggression in each situation. From Mischel and Shoda (1995, p. 249). verbally aggressive when warned by adults, leading observers to consider *why* he might react in particular to being warned, and the meaning of such warnings for that individual. Perhaps the child becomes embarrassed at being “shown up” by adults in front of peers, or loves to challenge authority and see how much he can get away with. Child 28, by contrast, becomes reliably aggressive when approaches socially by peers, inviting and suggesting a completely different set of explanations for his

behavior, for how the child construes the world, for what he may consider threatening, or what goals may motivate him.

As these examples illustrate, there is not a one-to-one correspondence between the outward behavior (e.g., aggression) and the underlying disposition. Instead, such profiles require explanations of another nature, and one that perceivers seem to engage in intuitively (Kammrath et al., 2005; Plaks et al., 2003): These profiles invite questions about how the target feels, what the target thinks, and how the target perceives his or her world. In the next section, we review the theoretical account that can account for such profiles, then detail the convergences of such a model with the premises of cultural psychology.

THE CULTURALLY CONSTITUTED COGNITIVE-AFFECTIVE PROCESSING SYSTEM

Having established *if . . . then . . .* signatures as a second, reliable locus of personality coherence, the task became to generate a framework that could account for both these profiles and overall aggregate behavioral tendencies. In response to this task, Mischel and Shoda (1995, 1999) proposed a Cognitive-Affective Personality System (CAPS) framework that integrates insights about knowledge activation (Anderson, 1988; Higgins, 1996; Hong & Mallorie, 2004; Kashima, 2001), social cognition (e.g., Cantor & Kihlstrom, 1989; Downey & Feldman, 1996; Read, Jones, & Miller, 1990), and connectionism (Hinton, McClelland, & Rumelhart, 1986; Kashima, 2004; Read & Miller, 1998, 2002). We describe the framework in some detail below as one representative of a family of approaches (see Cervone, 2004; Hong & Chiu, 2001; Kashima, 2001; Pervin, 2001; see also Hong, Wan, No, & Chiu, Chapter 13, this volume) that, rather than parsing causal forces in terms of what is “dance” versus “dancer,” demonstrates how personality processes and the mediating units proposed to account for them are *inherently* contextual in nature (see also Norenzayan et al., Chapter 23, this volume). Following the description of this general framework as it has been related to culture and personality (Mendoza-Denton et al., 1999), we extend and refine the framework to explicitly to take a system view of culture (Kitayama, 2002) into account.

Rather than being a theory of personality per se, CAPS theory is a general framework that outlines a set of principles. It proposes that human behavior is mediated by a set of cognitive-affective units (CAUs) organized within a stable network of activation. This network or organization, according to Mischel and Shoda (1995), constitutes the basic stable structure of the personality processing system and underlies the behavioral expressions that characterize the individual.

Common Units for Culture and Personality: CAUs

CAUs are conceptualized in terms of five relatively stable “person variables” that have been identified over a century of psychological research as playing an important role in social behavior generation (Cervone, 2004; Read et al., 1990; Mischel, 1973; Pervin, 2001). They are summarized in Table 7.1. The content of CAUs is determined through, and grounded in, the individual’s cultural context—what is taught by one’s family, what is valued by one’s community, and what is afforded by one’s culture (Kitayama, 2002; Mischel & Shoda 1995; Shoda, 1999).

CAUs provide a natural bridge to the study of culture as a result of their striking convergence with widely accepted definitions of culture. Classical, as well modern, definitions of culture consistently emphasize CAU-type constructs—

TABLE 7.1. Types of CAUs in the Personality Mediating System

1. *Encodings*: Categories (constructs) for the self, people, events, and situations (external and internal).
2. *Expectations and beliefs*: About the social world, about outcomes for behavior in particular situations, about one’s self-efficacy.
3. *Affects*: Feelings, emotions, and affective responses (including physiological reactions).
4. *Goals*: Desirable outcomes and affective states, aversive outcomes and affective states; goals and life projects.
5. *Competencies and self-regulatory plans*: Potential behaviors and scripts that one can do, and plans and strategies for organizing action and for affecting outcomes and one’s own behavior and internal states.

Note. From Mischel and Shoda (1995, p. 253). Copyright 1995 by the American Psychological Association. Reprinted by permission.

values, beliefs, meanings, customs, attributions, attitudes, and appraisals—as central components of the cultural heritage that is shared and transmitted among members of a given cultural group (Geertz, 1973; Obeyeskere, 1981; Schwartz, 1992; Triandis & Suh, 2002; Triandis et al., 1980; Tylor, 1871). There seems to be wide agreement that culture plays a large role in determining what is valued, what is worth pursuing, and how to interpret the world.

Given the correspondence between elements of culture and elements of a person, it is tempting to draw a one-to-one correspondence between “culture” and “person,” such that a person is viewed as a culture writ small, or its converse, that culture is “personality writ large” (Benedict, 1934). A moment’s thought, however, reveals a much more complicated relationship between “culture” and “person.” A person cannot be a “culture” writ small, because the person can be thought of as consisting of many little cultures—people are Thai, they are men, they are family men, they are husbands, they are colleagues at work—and each of these is its own distinct culture. The mutual influence of culture and person, then, operates at multiple levels, such that each person’s social circles dictate his or her unique social reality (Linton, 1936; Mendoza-Denton et al., 1999).

Culture and Principles of Knowledge Activation

As several researchers have noted (Kashima, 2001; Hong & Mallorie, 2004) principles of knowledge activation (Higgins, 1996) are helpful in thinking about the intersection between culture and personality. Members of cultural groups differ in terms of what goals, values, and beliefs are *available*. For example, whereas one culture may teach beliefs about spirit possession to its members, this notion may not be part of the explanatory repertoire for others’ behavior among members of other groups. The CAPS framework also assumes that people differ in the *chronic accessibility* (Higgins, 1996; Mischel & Shoda, 1995; Shoda, LeeTiernan, & Mischel, 2002) of constructs, that is, the ease with which particular CAUs become activated. For example, a strong cultural norm of valuing others’ welfare may make such a concern more chronically accessible—thus, easily activated—to individuals of that culture (e.g., Markus & Kitayama, 1991). As another example, by virtue of shared experiences, stigmatized group

members within a given culture may have concerns about discrimination more chronically accessible than nonstigmatized group members (Mendoza-Denton et al., 1997). Finally, the model also postulates that of all the beliefs, goals, values, encodings, and feelings that one can potentially experience at any given time, only those that are relevant in a given situation can become activated and influence subsequent behavior (Hong, Benet-Martinez, Chiu, & Morris, 2003). As such, CAPS makes specific the notion of *applicability*. For example, one cultural difference identified in prior research has been a greater tendency toward self-enhancement in the United States than in Japan (Heine et al., 1999), but this cultural difference is expressed in culturally defined situations and contexts. Another example comes from Kitayama, Markus, Matsumoto, and Norasakunkit (1997), who demonstrated that European Americans are highly self-enhancing, and this is especially true for situations that European Americans spontaneously nominate as being relevant to their self-esteem. By contrast, Japanese were found to be self-critical but, again, more pronouncedly so in situations identified by the ingroup as relevant to self-esteem. As such, culture influences personality through and through—not only in terms of the goals and important beliefs but also in the way that situations are represented and what psychological features situations contain.

Thinking about a box of crayons offers a metaphor for cultural influences and principles of knowledge activation. Culture dictates what constructs or CAUs an individual has at his or her disposal to color the world. If a given crayon (CAU) is not available, the person cannot use it. “Accessibility” refers to the ease with which a person is likely to use that crayon once it is available. If we imagine a box of crayons with three rows, for example, a person is more likely to use those crayons that are more easily reachable, such as the ones in front. Finally, “applicability” refers to the rules a culture dictates about what crayons one can use and when. A spirit possession “crayon”—if available—may be applicable to explaining mental illness in certain cultures but not in others.

Interconnections among CAUs

As Kitayama (2002) notes, “It is to be anticipated that cultures should be different not only in terms of central tendencies in any given vari-

ables but also in terms of functional relations among them” (p. 93). This quote captures the second important feature of CAPS, namely, that the person is not conceptualized only as the receptacle of disjointed, unrelated CAUs. Rather, CAUs operate within an interconnected *network* whereby CAUs have excitatory and inhibitory links to each other, and in which different pathways become activated in relation to features of the situation. For any given CAU, positive (excitatory) connections to it increase that CAUs activation level, whereas negative (inhibitory) connections to it decrease its activation level. A highly simplified, schematized version of a CAPS is shown in Figure 7.2.

The large circle in the middle of Figure 7.2 represents the “person,” whereas his or her stable network of CAUs is represented by the nodes and excitatory (solid lines) and inhibitory (dotted lines) links among those nodes. Al-

though the “network” of CAUs and interconnections is itself stable, as the individual moves across different situations, different mediating units and their characteristic interrelationships become activated (contingent on applicability) in relation to psychological features of those situations. The framework accounts for and is able to generate meaningfully patterned expression of behavior in relationship to situations, as well as to generalized overall tendencies in behavior (Shoda & Mischel, 1998). This is an important point, because it highlights the fact that the CAPS approach does not necessarily stand in contrast to broad differences between individuals (Mischel & Shoda, 1999).

Life experiences shared by members of a group—the teachings of elders, the experiences shared with others, the values imposed by society—generate a CAPS network that is immersed in and reflects the surrounding culture.

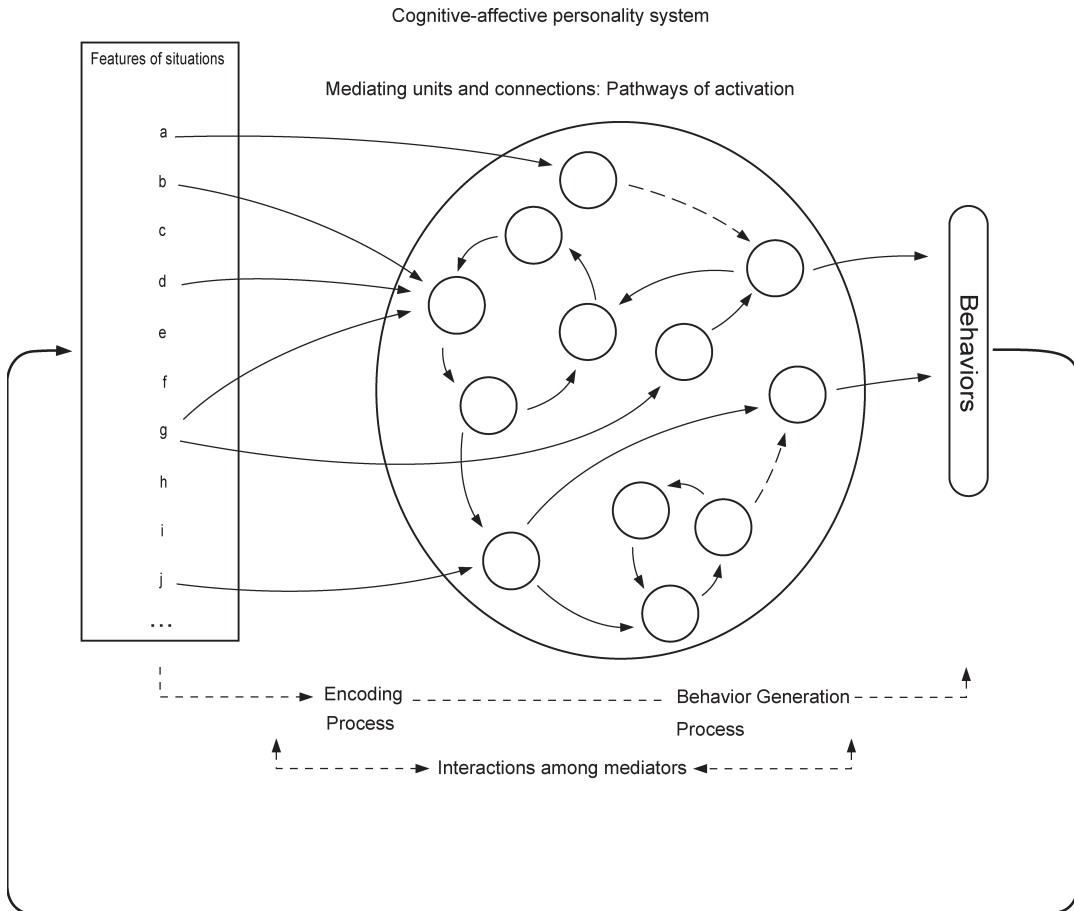

FIGURE 7.2. Schematic illustration of the CAPS. From Mischel and Shoda (1995, p. 254). Copyright 1995 by the American Psychological Association. Reprinted by permission.

If features of a situation activate this culturally shared subnetwork, an individual may generate similar reactions to that situation, without implications for the rest of the individual's distinctive processing dynamics (see also Cohen, 1997). In other words, when situations reliably activate shared networks, cultural commonalities in behavior may occur, whereas in situations that do not activate a culturally shared psychological feature, group members' responses may not converge (although they may converge with those of another group).

Consider one of the most striking examples of cultural convergence within the United States in recent memory—reactions to the 1995 verdict of the murder trial of the African American former football star and celebrity O. J. Simpson. At the time, it was clear that opinions regarding the defendant's guilt were sharply split along racial lines. An analysis of reactions to the verdict showed that, among African Americans, certain features of the case—such as the detective who planted evidence to influence a conviction—reliably activated cognitions about historically unfair police treatment toward African Americans in the United States. These cognitions, in turn, inhibited others, such as “There is a lot of evidence against the defendant.” European Americans, for whom the realities of race-based discrimination are both less available and less accessible, instead focused on the evidence—and held a strong belief that Simpson should have been found guilty. Indeed, the effect of race on reactions to the verdict was mediated by the shared network of cognitions activated (Mendoza-Denton et al., 1997). Of note, reactions to verdicts of other high-profile trials are generally not split along racial lines, suggesting that members of cultural groups can share subnetworks activated in some situations but do not have to display similarity in behavior to others.

AN INTEGRATED SYSTEM VIEW OF CULTURE AND PERSON DYNAMICS

Kitayama and colleagues (Kitayama, 2002; Kitayama & Markus, 1999; Kitayama et al., 1997) have contributed a perspective that adds another layer of complexity to our understanding of the co-constitution of person and culture. Similar to how we have argued for a dynamic and flexible view of personality in favor of a static, context-free view, a systems view of *culture* stands in contrast to static treatments

of cultures as explanatory, even causal entities that “account” for group differences (cf. Betancourt & López, 1993). The influence of culture on personality is broader, and its dynamics influence the person at several levels, such that culture is not just stored “in the head” (a view perhaps taken too easily taken from the earlier CAPS analysis) but rather limits, directs, and invites culturally consonant behavior in other ways.

A systems view of culture recognizes that cultural values and belief systems shape the institutions and everyday practices of a culture, which themselves provide *cultural affordances* (Kitayama & Markus, 1999) or opportunities for the expression and reinforcement of these cultural values. A core cultural belief system such as the Protestant work ethic (Levy, West, Ramirez, & Karafantis, 2006), for example, can give rise to institutions that reinforce its very unfolding, and influence the settings and situations that people navigate in their daily lives (Vandello & Cohen, 2004). In a similar way, a belief in personal mastery over the environment, or over nature, can lead to the valuation, and construction, of gymnasiums where such mastery and discipline become practicable and true (“physical culture”; Triandis et al., 1980). At the level of the individual, these macro-level influences lead to differences in the psychological availability of certain constructs (e.g., belief in mastery over aging), the (chronic) accessibility of these belief systems (through gyms, ads, and other artifacts serving to chronically prime ideas of beauty, health, and youth), as well as the organization among the cognitions and affective evaluations. As such, then, a system view of culture reminds us that culture not only influences the content of the box of crayons people use to “color their world” but in fact also influences the coloring book itself.

A Schematized View of the C-CAPS Model

The Cultural Cognitive–Affective Processing System (C-CAPS) model is one in which a system view of culture and a system view of the person are integrated and explicitly acknowledged to influence each other. Figure 7.3 provides a schematic view of this multisystem model: This section walks the reader through Figure 7.3. We begin with the three boxes on the left-hand side—subjective culture, physical culture, and nominal situations. As a whole, they make up the cultural affordance processes

that not only shape the CAPS system but also constrain the kinds of situations to which the CAPS system is exposed. “Subjective culture” is the term that Triandis and colleagues (1980) have used to refer to the cultural beliefs, values, and meaning systems that become transmitted from one generation to the next. Examples of such cultural values might be the “Protestant work ethic” (PWE; Levy et al., 2006), “social dominance orientation” (Pratto, Sidanius, Stallworth, & Malle, 1994), or “collectivism” (Triandis, 1996). Subjective culture is likely to influence directly the availability, accessibility, and network relationships of the person’s own beliefs, values, and goals (arrow 1 in Figure 7.3). The cultural value referred to abstractly as “PWE,” for example, might be cognitively represented in terms of concrete cognitions such as “Be all you can be,” “Hard work pays off,” or “No pain, no gain” (see Geertz, 1973, for a discussion of abstract value systems vs. more concrete, or “experience-near” cognitive representations). Arrow 2 captures the notion

that cultural value systems influence people’s physical surroundings—the types of institutions that are built, for example, or the architectural designs that foster culturally valued types of social interaction. This arrow is bidirectional to reflect the notion that physical culture also reifies the cultural value systems that create and maintain it. As arrow 3 shows, cultural belief systems and institutions then afford group members the specific nominal situations that allow people to practice and further reinforce those belief systems as part of a shared reality. These nominal situations are more discretionary, temporally discrete instantiations of culture, such as taking an exam, running on a treadmill, or having a power lunch with a client.

Together, these first three boxes in Figure 7.3 take us from a broader “culture” to a more specific “context,” to a more specific “situation,” although these distinctions themselves do not have clean, easy boundaries. Although the “power of the situation” is great (see Ross

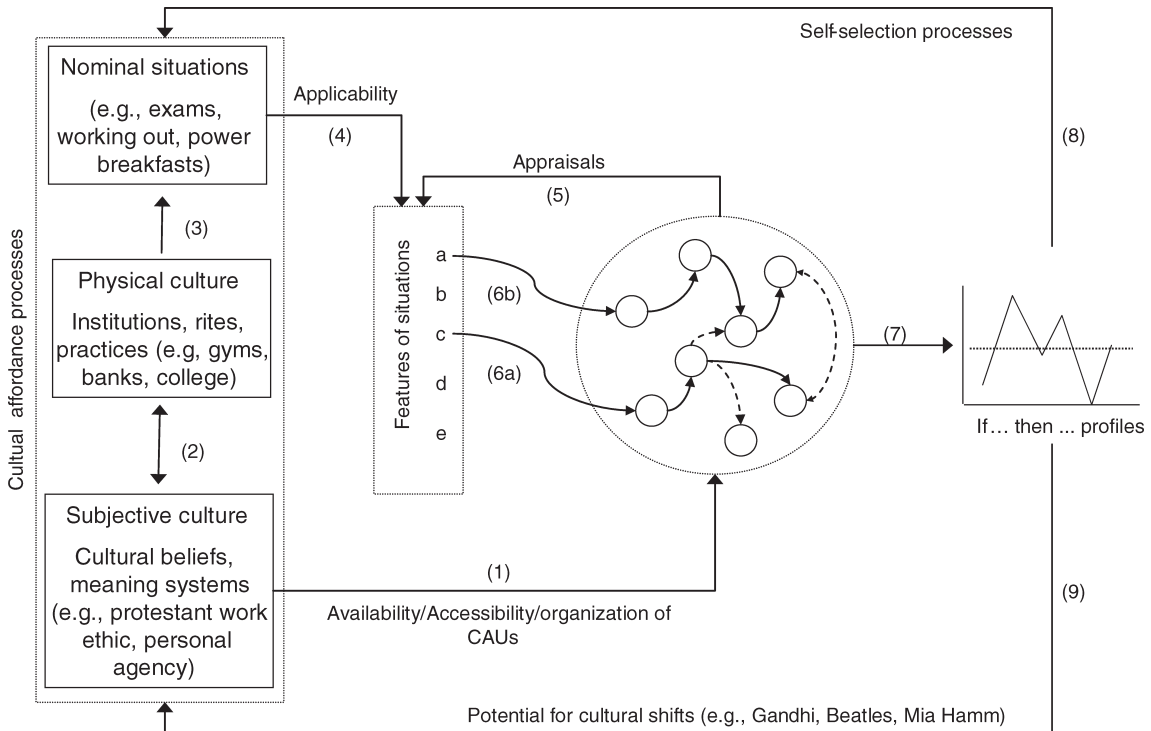

FIGURE 7.3. Schematic illustration of the culturally constituted C-CAPS. Subjective and physical culture influence the contents and organization of the individual’s processing system (1), and provide the cultural affordances that form a basis for the nominal situations experienced by the person (2, 3). Psychological features of situations are influenced by both nominal situations and the person’s appraisal processes (4, 5). The system yields *if . . . then . . .* signatures (6a, 6b, 7), which both influence the immediate environment of the person (8) and have the potential to enact cultural change (9).

& Nisbett, 1991), even these “situations” cannot be separated from the people who collectively, as a culture, have defined and continue to define them.

Arrows 4 and 5 in Figure 7.3 reflect the constitutive influence of culture and the person as reflected in the psychological situation (Shoda et al., 1994). As discussed earlier, the subjective meaning of a nominal situation is influenced by the person’s existing knowledge structures through appraisal processes (arrow 5; see Cervone, 2004); however, appraisals are bound to and directed by their *applicability* to a given nominal situation (arrow 4). As in the original CAPS formulation, features of the psychological situation then activate and inhibit other CAUs (arrows 6a and 6b), following a pattern of activation and inhibition such that *if . . . then . . .* profiles, as well as overall behavior tendencies, are displayed (arrow 7). As various researchers have argued, these behaviors then influence the very situations in which people find themselves in (Levy, Ayduk, & Downey, 2001), creating a self-selection bias (arrow 8). For example, the person who believes in personal agency and control over aging is likely to find him- or herself working out, and encoding the experience as daily mastery against old age. Thus, culture and the person are both interpenetrating each other, mutually discernible yet inseparable.

Finally, arrow 9 in Figure 7.3 provides the possibility that people can alter subjective or physical culture. Gandhi inspired and mobilized entire groups of people toward a belief in the power of peace; the Beatles changed the meaning of music; Mia Hamm played soccer at a moment in history when a nation (in this case, the United States) was ready to get serious about women and sports. Thus, individuals can also influence the normative forces we call “culture.”

TWO ILLUSTRATIONS

The stable situation–behavior profiles generated by the CAPS system lend themselves not only to the idiographic study of persons but also provide a nomothetic route to characterize cultural groups in terms of their shared subnetworks, situation–behavior signatures, and common cultural affordances. In the section that follows, we briefly illustrate some ways that a dynamic system approach to culture and personality can help shed light on cul-

tural convergences in behavior. The emphasis in these approaches is in a deeper understanding of how history, cultural meaning systems, and contextual constraints shape the thoughts, cognitions, and affects that individuals experience. We choose two examples—research on culture of honor, and on race-based rejection sensitivity—to illustrate how macro-level forces such as a herding economy or a history of discrimination against one’s group shape the social-cognitive worlds of individuals.

Culture of Honor

Research on culture of honor (Cohen, 1998; Cohen, Nisbett, Bowdle, & Schwarz, 1996; Nisbett & Cohen, 1996; see also Cohen, Chapter 8, this volume) provides an in-depth analysis of how historical forces shape cultural practices and norms (cultural affordances), which in turn influence the way individuals behave in particular situations (person \times situation interactions). The research provides an excellent illustration of how seemingly contradictory surface-level behaviors can be understood, and subsequently predicted, by understanding how subjective and physical culture have shaped the characteristic cognitions, affects, and encodings characteristic of a given group within the United States.

What are these contradictory surface-level behaviors? As Cohen et al. (1996) noted, “For centuries, the American South has been regarded as more violent than the North” (p. 945). Consistent with this reputation, rates in the South and West for argument-related homicides have been shown to be higher than they are in the North (Nisbett & Cohen, 1996). Despite this reputation, however, Southerners also have a reputation for being charming and polite. A recent etiquette expert ranked Charleston, South Carolina, as the nation’s most polite city—for the 10th straight year. “When you pass people on the street, they will nod at you,” reports a Charleston city tour guide. “People who live here are, for whatever reason, polite. Whether it’s breeding or in the water, it’s hard to say” (CNN, 2005). In short, the South’s reputation for violence stands alongside its equally strong reputation for politeness, for that old Southern charm. How then, do we reconcile the view of a violent South with a view of a charming South?

According to the culture of honor hypothesis, a herding economy in combination with loose law enforcement in the Southern and

Western United States have led to a cultural adaptation in which honor and reputation have become critical elements in the protection of one's property and name. In the absence of adequate social control, it became important to respond quickly and affirmatively to being crossed, insulted, affronted, or stolen from, so as to communicate to the community not to "mess" with one's property and to maintain one's status. The culture of honor, characterized by strong vigilance to disrespect and ready use of violence to protect property and name, has over time affected social practices and norms. This is symbolized both in games that amount to tests of "manhood" (e.g., "chicken" games, or kicking each other in the shins) and in legal lenience toward violence instigated by affronts to honor (Cohen & Nisbett, 1994, 1997). These practices and laws are good examples of the way subjective culture influences physical culture, as illustrated by arrow 2 in Figure 7.3.

As Cohen, Vandello, Puente, and Rantilla (1999) explain, a culture of honor that rests on violent retaliation following affront dictates not only how to react when such an affront occurs, but also how to act when an affront does *not* occur. More specifically, in a culture where serious retribution is a consequence of disrespect, it is to one's best interest to be unambiguous about according respect when one is not looking for trouble. As such, then, a distinct *if . . . then . . .* pattern can be viewed as characterizing the behavior of people sharing a culture of honor.

In a laboratory-based "experimental ethnography" that provided empirical support for this culture of honor profile, Cohen and colleagues (1996, Study 3) recruited Northern and Southern white men to participate in a laboratory study generally described to be about personality. An ingenious experimental manipulation followed. Participants were brought into the lab, asked to fill out questionnaires, and then drop off the packet at the end of a long, narrow hallway. Half of the Southern and half of the Northern participants were then subjected to an affront: While walking down the hallway, they had to squeeze past an assistant (in reality, a confederate) getting something out of a cabinet. The confederate, feigning annoyance, slammed the cabinet shut, insulted the participant under his breath, and intentionally bumped the participant on his way out of the hallway. At this point, the participant still had to make his way to the end of the hallway, but

at this point a different person (also a confederate) began walking down the hall toward him. Given the width of the hallway, this in effect set the stage for a potential game of "chicken," where the point is to see who swerves out of the way first. The distance at which the participant "chickened out" or got out of the confederate's way was expected to vary both as a function of the participant's background and whether he had been bumped or not. Following this encounter, the participant finally made it to the end of the hall, where he was met by a different confederate. This confederate, blind to the regional background of the participant, rated the firmness of the participant's handshake and gave an overall impression of the participant's domineering behavior.

As expected, and corroborating prior research, Southern men who had been bumped, relative to men from the North, waited longer before stepping aside to let the second confederate through. This is consistent with the interpretation that following an affront (the bump by the first confederate), a more aggressive response to restore honor was facilitated among Southern men. Participants were also rated by the third confederate as more aggressive and dominant, and as giving a firmer handshake relative to that of Northern participants. Tellingly, however, among participants who had not been bumped, the Southern men were more "polite" than their Northern counterparts: They got out of the second confederate's way earlier, gave less firm handshakes, and were less domineering and aggressive with the third confederate.

Thus the results from this study are consistent both with the notion that Southerners are more violent, and that Southerners are more polite. Which one is correct? The answer is both—a clear *if . . . then . . .* pattern, predicted from an in-depth analysis of the historical and social influences affecting the South, as well as astute expectations as to how those macro-level influences affect the way individuals construe and respond to situations. Importantly, a global analysis of Southern aggression without regard to the situation would miss these dynamics entirely.

Mere Recategorization, or Dynamic Complexity?

Cultural psychologists might worry about a characterization—or caricaturization—of Southern "personality" as a two-point pattern dictated by respect and affront, where

the stable aspect of the person, instead of being a global adjective, is now conveniently replaced by a global belief system or even a set of folk beliefs. However, it is important to remember that the C-CAPS—the shared networks of beliefs, cognitions, affects, and actions, activated in relation to situations—exist within a broader network that may or may not be shared by other members of the group (Kashima, 2004). For example, while two men may both have grown up in the South, and may both feel physiological arousal when verbally insulted in a hallway (Cohen et al., 1996), one of these two men may consider self-control an important life value, perhaps as a result of martial arts classes, or a deep religious conviction of “turning the other cheek.”

Although efforts toward a contextual analysis of behavior within cultural and cross-cultural psychology have an established history (Hoorens & Poortinga, 2000), such analyses have been criticized (Shweder, 1991) as conveniently recategorizing people into smaller and smaller groups every time a prediction goes awry (e.g., where insights about “Southern men” become insights about “Southern men who hold deep religious beliefs” and eventually “Southern men who hold deep religious beliefs but who have self-regulatory competency”). By contrast, a view of the culture–personality system as a dynamic network allows us to understand how one can reconcile both cultural homogeneity and difference *as part of the same dynamic process*. The strength of the C-CAPS lies in its recognition that an individual who can behave similarly to others in his or her cultural group, when the correct psychological features of situations are activated, can act in a completely idiosyncratic manner when a different set of features is activated, thus allowing for individuality and commonality within the same individual at different times (Mendoza-Denton et al., 1997). Thus, rather than an atheoretical recategorization of behavioral responses into smaller and smaller groups, The C-CAPS view focuses on the stability of the *if . . . then . . .* Culture–personality profiles, and their diagnostic use toward a deeper understanding of the interplay between cultural conditions and processing dynamics. The level of specificity adopted with C-CAPS is a *choice* that depends entirely on the goals for which it is used, all the way from the individual life history (McAdams, 1999) to large group and cultural comparisons.

Race-Based Rejection Sensitivity

To this point, we have provided illustrative examples of C-CAPS, such that particular features of situations (e.g., an affront to honor, or a crooked cop planting evidence) activate culturally shared dynamics that predict behavior by members of a cultural group. There is the possibility, however, of variability even in situations that seem especially relevant to cultural groups. This variability can be fruitfully harnessed to understand and map a given cultural dynamic—in other words, individual differences providing a window into psychological process (Mendoza-Denton, Page-Gould, & Pietrzak, 2006). One example of this is work on sensitivity to race-based rejection in the U.S. context, in which clear, within-group variability coexists with a dynamic predicated on particular experiences being more likely to occur to members of a particular group.

As several researchers have emphasized, the psychology of minority group members must be understood within the group’s own context and historical background, an important part of which is a history of stigmatization and the continuing discrimination that exists to this day (Sellers, Caldwell, Schmeelk-Cone, & Zimmerman, 2003; Shelton, 2000). This history, as well as prior experiences, are likely to affect individuals in profound ways, affecting both the sense of self (Humphreys & Kashima, 2002; Mischel & Morf, 2003; Kashima et al., 2004) and the stable responses that the individual marshals in response to discrimination. One such mechanism, termed *sensitivity to race-based rejection* (RS-race; Mendoza-Denton, Downey, Purdie, Davis, & Pietrzak, 2002; Mendoza-Denton et al., 2005) also illustrates the intricate co-constitution of culture (societal stereotypes and prejudice), nominal situations (e.g., the university setting), and the person (RS-race dynamic).

Growing out of developmental perspectives on attachment, the construct of RS-race has its theoretical precursors in research on rejection sensitivity (Downey & Feldman, 1996; Levy et al., 2001). Based on a series of prospective, longitudinal, and experimental studies, Downey and colleagues have proposed that when people experience rejection from parents, peers, or other important figures in the form of abuse or neglect, they are vulnerable to developing anxious expectations of rejection, namely, a “hot,” affectively laden expectation that future rejection lies in store in similar kinds of situations.

These anxious expectations are activated in situations where rejection is both applicable and salient (Higgins, 1996), and is a good illustration of the idea that the stable dispositional feature of the individual, namely, anxious expectations, are made accessible specifically in relation to features of the situations. Ayduk, Downey, Testa, Yen, and Shoda (1999), for example, found that when rejection-sensitive women were rejected, they retaliated by bad-mouthing the perpetrator; however, when an alternative, benign explanation for the rejection was offered, no retaliation was observed. These anxious expectations lower the threshold for perceiving the rejection and, once the rejection is perceived, activate intense, “hot” reactions to it.

To the degree that affiliation and acceptance can be considered a fundamental human motive (Fiske, 2004), people may be universally capable of developing the dynamic of rejection sensitivity (anxious expectations → ready perceptions → hot reactions) if rejected or neglected. However, the manifestation of rejection may be expressed in many different ways that are constrained by culture. Mendoza-Denton and colleagues (2002) postulated that rejection can occur on the basis of not only idiosyncratic characteristics but also devalued group membership—such as gender, sexual orientation, or race.

Cultural influences come into play at several levels. First, as has been widely recognized, stigma is context-specific: An attribute or personal characteristic that is devalued in one domain may be valued (or be neutrally valenced) in another context (Crocker, Major, & Steele, 1998). As such, the context within which a person operates can dictate the type of interpersonal experiences—and stable dynamics—that develop as a result. Second, even when two groups might be negatively stigmatized, the nature of the stigma depends on the assumptions that a given stigma carries about one’s group. In the United States, for example, being African American carries a suspicion about academic inability (Steele, 1997), but not about athletic ability, whereas the reverse is true of Asian Americans (Chan & Mendoza-Denton, 2004). As such, then, although two people may be equally apprehensive concerning their status, the situations that activate their rejection concerns are different. Finally, the coping mechanisms applied in response to the rejection may be different. Again, one’s cultural group pro-

vides one with culture-specific strategies, values, and culturally appropriate strategies marshaled in response to rejection.

If one takes such a cultural-psychological analysis seriously, it becomes difficult, if not impossible, to create a technique to assess status-based rejection expectations *independently* of context. Accordingly, Mendoza-Denton et al. (2002) conducted focus groups to find out the situations that activate race-based rejection concerns among African Americans, and constructed a questionnaire based specifically on those situations (this methodology parallels Kitayama et al.’s (1997) situation sampling procedure). The kinds of situations included scenarios such as a random traffic stop or being passed over for an opportunity to answer a difficult question in class—situations that contain “active ingredients” for making discrimination applicable and salient among African Americans. The researchers administered this questionnaire to a sample of African American, European American, and Asian American undergraduates. As expected, African Americans scored highest on the measure, whereas European American and Asian American participants scored low and did not differ. Individual differences in the measure predicted spontaneous attributions to race in these situations among African Americans but not among European Americans or Asian Americans (Mendoza-Denton et al., 2002). among African Americans, individual differences in anxious expectations of race-based rejection subsequently predicted, over a 3-week period, reports of rejection, and more intense feelings of alienation and rejection following the rejection. Over the course of five semesters, individual differences in RS-race among African Americans predicted students’ grade point averages (GPAs). This last result in particular illustrates well how culture is both “in the head” and “out there.” Individuals enact self-protective mechanisms in response to discrimination, which, at a system level, is maintained by the broader culture’s subjective culture (e.g., stereotypes, system justifications), physical culture (majority-dominated college settings), and nominal settings (unequal opportunities). Rather than being a question about explaining the phenomenon either through social or personality psychology, this approach shows not only their inseparability but also the indispensability of their interplay for an understanding of the dynamic.

It may be helpful at this point to consider a hypothetical scenario in which two Americans—one black, one white—score equally highly on a measure of neuroticism, but in one case the score is capturing the individual's concerns surrounding societal discrimination, whereas in the other the score is capturing the individual's concern surrounding romantic relationships. Far from being mere “adaptations” (McCrae, 2000), not to be confused with dispositions, we argue that it is *precisely* by knowing about the trigger features, the outcomes, and the historical context surrounding the behavior of each person that one begins really to arrive at the cultural psychology underlying social behavior (Cohen, 1997; Mendoza-Denton et al., 1997). A deep understanding of people's responses to the particular predicament in question depends on cultural background, as well as cognitive-social learning history—in one case, a strong historical backdrop of oppression and discrimination (Mendoza-Denton et al., 2002) and in the other, perhaps neglect or abuse in the home (Downey & Feldman, 1996). To draw on an earlier analogy, the only way to distinguish between the two cars is by looking under the hood.

IMPLICATIONS

Assessment Issues

Having provided two illustrations of how the C-CAPS operates, we now turn to a discussion of personality assessment through a cultural-psychological lens. As noted earlier, the current dominant approach to personality assessment and comparison across cultures is the global trait approach (Triandis & Suh, 2002), which is both helpful and attractive because it provides a rigorous, methodologically driven approach to assessment. However, as we have noted, aggregating or ignoring situational variability in behavior necessarily precludes an analysis of the ways in which personality dynamics and culture influence one another.

But how should situations be grouped? This is the critical question for a viable cultural-psychological approach to personality. As reviewed earlier, this approach suggests that rather than looking at nominal situations (e.g., the marketplace, the university, a social chat around the water cooler) that are of limited generalizability (e.g., see B. B. Whiting & Whiting, 1975), people act on situations that are *psychologically* similar (e.g., contexts that

are ripe for social rejection; opportunities in which one can advance one's children's education). The distinction between nominal and psychological situations lies precisely at the heart of a cultural psychology in which the world outside is interpreted through the lens of the culture, and those interpretations are themselves facilitated through cultural affordances. To the degree that psychological situational groupings are culturally specific, it is the task of the cultural psychologist to uncover those local meanings and not be lured by outward appearances. As some of the research summarized in this chapter illustrates, personality processes as they are embedded and expressed in their cultural context can be captured with various methodologies.

Bottom-Up Approaches

As described earlier, Wright and Mischel (1988) used clustering techniques to identify different types of commonly used situational modifiers that the cultural experts in that context (the targets' peers and counselors) used to describe a particular cultural group. This is an example of a “bottom-up” strategy, in which the researcher recruits “experts” or informants in a given culture to provide the raw data for subsequent coding and clustering.

Top-Down Approaches

A second, “top-down” approach to assessment is one in which the researcher begins with a theory of the internal processing dynamics that may characterize a type, and is then able to hypothesize the distinctive *if . . . then . . .* profile for that type, as well as the psychological trigger features that define the profile (e.g., Downey & Feldman, 1996). A theory about a cultural group's distinctive processing dynamics can be derived from careful study about a group's history, or the social, environmental, and historical forces that have shaped its people. An excellent example of this approach is the careful analysis leading to the culture of honor research reviewed earlier. A hybrid approach, containing elements of both a top-down and a bottom-up approach, is seen in Mendoza-Denton et al. (2002), who not only hypothesized the dynamic of RS-race on the basis of historical and societal analysis but also interviewed people about the specific situations in which the dynamic would be played out.

Interpreting Cross-Cultural Differences in Global Traits

Researchers have shown quite convincingly that there are trait-level differences among cultural groups (Triandis & Suh, 2002). Again, the proposed approach is not incompatible: The C-CAPS predicts, and is able to account for, both *if . . . then . . .* patterns and broad differences between groups. In considering findings that two cultural groups differ—or do not—on a given trait, however, the C-CAPS approach uncovers alternative interpretations to a one-to-one correspondence between the trait and underlying dispositions.

Consider findings from Kammrath et al. (2005, Study 3), who presented people with several distinct *if . . . then . . .* patterns that were nevertheless identical in their overall interpersonal warmth. For example, one target was reliably friendlier toward authority figures than to peers, whereas a second target displayed precisely the opposite pattern. A third target was not differentially friendly toward authorities and peers. Participants rated their impressions of each target using Goldberg's transparent, bipolar Big Five scale (Goldberg, 1992). From a global trait perspective, people should rate all targets equally on Agreeableness and Extraversion, given that all targets displayed the same overall level of interpersonal warmth. The results showed that although ratings of Extraversion did not differ across the three targets, the target that was warm toward authorities was seen as distinctly disagreeable, whereas the target that was friendly to peers was rated as quite agreeable (the third target was rated in the middle). These findings suggest caution in interpreting broad trait dimensions as indexes of overall behavior aggregates. In the research described here, the targets did *not* actually differ in their overall warmth, despite clear differences in perceivers' ratings of their Agreeableness.

A second caution in interpreting trait-level cultural differences too literally is seen in Shoda, Mischel, and Wright (1993), who also analyzed data from the boys' summer camp described earlier (Shoda et al., 1994; Wright & Mischel, 1988). For this analysis, the researchers analyzed the *if . . . then . . .* profile patterns of those boys who were collectively agreed to be prototypical exemplars of "friendly," "withdrawn," and "aggressive" children. Surprisingly, when looking at the children's physical

aggression, it was not the prototypically "aggressive" children who displayed the most overall physical aggression—it was the campers labeled as "withdrawn." Evidently, even though the perceivers used the label "aggressive" to describe children and agreed as to which children could be described this way, the specific pattern to which the label referred did not necessarily correspond to the surface-level behavior. As another example, consider findings on gender stereotypes by Mendoza-Denton, Park, Kammrath, and Peake (2004). Despite the fact that men are stereotypically labeled as "assertive" and women as "passive," Mendoza-Denton et al. found that women are in fact expected to be more assertive than men in certain situations (e.g., those that have to do with home and hearth). The relevant point is that perceivers' labels do not necessarily correspond to the surface-level manifestations of behavior that the labels suggest.

As these examples suggest, the relationship between the trait terms people use to describe others and the behavior patterns to which they relate is not straightforward. People undeniably use traits, and the basic classification of these into five categories seems to have solid support, but their interpretation as reflecting biological dispositions of entire cultural groups (e.g., McCrae, 2004) seems premature. Having identified through careful, rigorous work that some groups of people differ from others in the traits ascribed to them, the logical next step seems not to look for biological differences, but rather to understand cultural variability in the lay theories associated with these traits.

CONCLUSIONS

In the seminal article "Cultural Psychology: What Is It?" Shweder (1990) refers to a song by Paul McCartney and Stevie Wonder, "Ebony and Ivory," with the lyric, "We all know that people are the same wherever you go." Shweder cites this lyric as an example of the intuitive lay notion, based on Platonic philosophy, of psychic unity—in other words, the idea that in spite of cultural superficialities, a basic humanity unites all of us (see Triandis, Chapter 3, this volume). In current cross-cultural conceptualizations, such psychic unity is claimed to be a universal personality trait structure that goes above and beyond cultural differences—with the strong implication that, indeed, people

are the same wherever you go. Cultural psychology has suggested an alternative path to this approach, rejecting the notion of psychic unity and instead preferring to show that, by virtue of the fact that culture and psyche make each other up, people are just, irreducibly, not the same wherever you go.

And yet McCartney and Wonder do seem to have a fundamental point that cannot be easily dismissed. It stands to reason that, as a species, there should be a set of characteristics that unites all of us. Within the C-CAPS framework, the potential candidates for universality are the basic architecture of the system and its governing principles—availability, accessibility, applicability, and organization.

Despite calls not to equate personality exclusively with global traits, and warnings about the utility and comparability of broad constructs across cultures (Bock, 2000; Church, 2000; Kashima, 2001; Pervin, 1999), the tacit equation of consistency with “individual behavior dispositions that are expressed as consistent behavior across time and across situations” (Poortinga & Van Hemert, 2001, p. 1034) remains, in our reading, the default assumption among researchers interested in culture and personality. The cost of this assumption for the study of culture and personality is that it bypasses some of the most exciting advances in current personality science, and obscures opportunities for integration (Church, 2000; Mischel, 2004; Shoda & Mischel, 2000; Shoda et al., 2002; Triandis, 2000).

We have proposed here that a processing model that can account for person \times situation interactions may be fruitfully applied to understanding how culture and person are mutually constitutive. This model departs from the classic notion of a bounded, causal entity called a “person” that exerts a unidirectional causal influence on behavior independent of situational or cultural forces. The framework offers a perspective that legitimizes cross-situational variability in behavior as the output of a culturally imbued, dynamic, meaning-making process (see Norenzayan et al., Chapter 23, this volume). It identifies an alternative set of mediating units—and their interrelationships—as the active ingredients of a cultural personality system. The cognitive–affective units and contextual variables outlined in Figure 7.3 are framed at a broad level, and require specification at the level of CAU contents and contextual variables to be able to offer prediction. In terms of the

contents and cultural manifestations of the C-CAPS, Shweder’s (1991) description could not be more apt: “The mind, left to its own devices, is mindless” (p. 83).

Thus, rather than itself specifying a set of predictions, the C-CAPS framework offers a set of principles that researchers can use to guide their theory-building work. Such theory building, as we have reviewed, can occur in both a top-down or a bottom-up approach, but likely requires as a first step intimacy with a cultural group, through either observation or the insights of cultural informants (see also Cohen, Chapter 8, this volume). We have argued that insights in social cognition and personality science over the past two decades provide a set of principles for research that can lead to a cumulative science of culture–personality studies. A failure to take them into account risks falling prey to overgeneralizations and untenable stereotyping that in the past yielded studies of “national character” (Benedict, 1934) and “modal personality” (DuBois, 1944) ultimately untenable (see Triandis, Chapter 3, this volume).

CHAPTER 8

Methods in Cultural Psychology

DOV COHEN

Cultural psychologists who approach phenomena from, say, a social-psychological, developmental, or anthropological perspective not only inherit all the methodological problems and issues from their home disciplines, but also acquire many new ones. Studying a topic in more than one culture brings some special complexities. Furthermore, some standard methodological problems that are by and large ignored in one's home discipline (e.g., subject sampling) become major issues in cultural-psychological research. In contrast, very few (or perhaps no) methodological problems become easier when culture is added to the picture.

This chapter attempts to make explicit some of the methodological issues that pose extra challenges for cultural researchers. As with other research, the methodological challenges center around four themes: Causality, Operationalization, Sampling, and Interpretation (COSI). In brief, these four themes involve the questions: "Can I determine causality?", "What is my independent variable 'doing' to people, and/or what does my dependent variable actually measure?", "To what populations can I generalize my results?", and "Am I reading the data correctly?" (See summary in Table 8.1.)

This chapter is not an exhaustive list of issues cultural psychologists face, and it does not cover the methodological concerns of qualitative research. Rather, it starts exploring the four COSI questions by asking 10 subquestions. Richard Lewontin (1995) observed that scientists spend a great deal of time talking about methodological issues to which their field has cogent answers, and ignore those for which they do not have cogent answers. The list of subquestions below has some of both types of issues.

With respect to *causal* issues involving cultural differences, the subquestions we address have to do with determining (1) "What is the cultural dimension driving my differences?"; (2) "Are my cultural effects driven more by things that are 'in the head,' 'out in the world,' or some combination of both; and if so, how should I measure such effects?"; and (3) "What ecological, economic, or historical circumstances caused the cultural difference to emerge in the first place?"

With respect to the issue of participant *sampling*, the subquestions addressed are (1) "What population can I sensibly generalize about?" and (2) "How do I think about what is 'culture' and what is 'confound' when I pick my sample for study?"

TABLE 8.1. COSI: Four Questions Asked by a Young Field

Or, why is this discipline different from other disciplines in . . .

Causation

Cultural psychologists need to think in terms of multiple equilibria (rather than, or in addition to, straight correlational thinking). A cultural syndrome (e.g., collectivism) may be sensibly associated with one pattern of behavior in culture A (e.g., low emotional expressiveness, balanced affect) and the opposite sort of behavior in culture B (e.g., high emotional expressiveness, high positive affect). Multiple equilibria map onto multiple meaning systems that can be sensible, coherent, and follow their own cultural logics.

In understanding culture, we can locate causality inside the person (social-cognitive approaches, individual difference approaches), outside the person (situational-structural-practice approaches), and in the interaction between person and environment (culture X person X situation approaches, syndrome approaches).

Equilibrium does not equal adaptation, though functional explanations of cultural patterns may be a good place to start.

Operationalization

Cultural psychologists have to operationalize constructs in ways that are convincing and interpretable when seen through (at least) two different cultural lenses. Thus, they face the broad challenge of “translation” (of languages, situations, behaviors, reference groups, etc.) across cultures.

Cultural psychologists do have an advantage, though, in that the field’s methodological pluralism gives researchers a full tool kit (e.g., surveys, laboratory experiments, field studies, analyses of cultural products, and more qualitative work) to produce convincing, convergent evidence, in which the strengths of one method offset the weaknesses of other methods.

Sampling

Cultural psychologists take the issue of participant sampling seriously. (That is the basis of our critique of mainstream psychology as primarily a psychology of the West). In the absence of probability sampling, however, how can one say something useful about either big-C Culture (American culture, Chinese culture, etc.) or little-c culture (the process by which people shape and are shaped by their world)? There are at least four different and contrasting sampling approaches to consider: typicality sampling versus just minimal difference sampling, and expert sampling versus inversion sampling. In thinking about which sampling approach to use, cultural psychologists need to think through some potentially thorny conceptual issues (e.g., what is culture, and what is confound?).

Interpretation

Cultural psychologists look at the “Necker cube” of culture, in which similarities are embedded within differences, and differences are embedded within similarities. Making the “familiar unfamiliar and the unfamiliar familiar” can reduce tendencies toward invidious comparisons with the Other. It softens comparisons and gets us out of our own frame of reference. Cultural psychology is about finding out how other ways of seeing the world (besides one’s own) can be meaningful, sensible, and coherent.

The key to any convincing explanation is convergent evidence across methods. However, evidence that does not converge may also point to interesting cultural phenomena.

With respect to *operationalization*, the three subquestions are (1) “Am I ‘translating’ my variable correctly from one culture to another?”; (2) “What are the cost-benefit trade-offs of surveys versus experiments?”; and (3) “What other methods can provide convergent evidence?”

Finally, with respect to *interpretation*, the two subquestions are (1) “Am I really understanding what is similar and what is different in the cultures?” and (2) “Even if convergent evidence from multiple methods is the answer to

most of my methodological problems, what happens if my evidence does not converge?”

The boundaries of the four elements of COSI can be quite fuzzy. However, for purposes of clarity in this chapter, the four elements are addressed in turn. The issues with causality are the most theoretical, the trickiest, and the ones that have the least cogent answers. The chapter begins with those as a starting point, because they lead into the sampling and operationalization issues. The O and S issues are more nuts-and-bolts and the answers to them are

more (but not completely) cogent, with the ultimate answer lying in the need to collect converging evidence across a variety of methods. Finally, the chapter ends with interpretation issues, which are more abstract and have some larger implications for how we think about culture.

CAUSALITY

Leaving Terra Firma

Any study without a randomly assigned independent variable is by definition a correlational study and can therefore never prove causality. The vast majority of studies in cultural psychology fit into this correlational category, because culture is not a manipulated variable. We make statements such as “The Japanese were more likely to emphasize duties and the Americans, more likely to emphasize rights, *because* Japanese and American cultures differ in how they view the individual and the collectivity” or “Cultures A and B value harmony, *because* their agricultural practices require them to work together.” These claims can be only suggested by our data. Nevertheless, a good portion of cultural studies make such causal claims (particularly of the first type); and using solid methodology often makes the difference between a strong suggestion of causality and a weak one.

Descriptive Studies

Studies in cultural psychology are often, but not always, of two different forms. One form is: Culture 1 has cultural syndrome X, whereas Culture 2 has syndrome Y. (Or sometimes, it is simply that Culture 1 has syndrome X, whereas Culture 2 does not). Examples of this sort of study are those showing that Eastern cultures tend to be more collectivistic, whereas Western cultures tend to be more individualistic, or that the South of the United States has a culture of honor, whereas the North of the United States does not (or has instead a culture of “dignity”).

These studies may be purely descriptive, outlining the cultural patterns in one society versus another. The measured variables here tend to be face-valid representations of the cultural difference one is studying. So a researcher may offer evidence that Mexican culture is more collectivist than American culture by showing that they differ on an individualism–collectivism

scale, that they think about and behave toward ingroups and outgroups differently, or that they differ in how much they identify with their ingroups. Such evidence is descriptive because the measured (or “outcome”) variable flows tautologically from the definition of individualism and collectivism. Furthermore, a researcher might conduct studies into the phenomenological experiences of people in a culture, explore a given cultural characteristic in depth, examine how this cultural characteristic manifests itself within a society or across societies, or study how cultural characteristic X is related to cultural characteristic Y (without worrying about causal direction; Asch, 1952/1987; D. Cohen, 2001; D. Cohen, Hoshino-Browne, & Leung, 2007; MacLeod, 1947; Rozin, 2001; Shweder, 1997). In such purely descriptive studies, no causal claims are made. As Rozin (2001) has pointed out, these studies are often a sensible place to start. More mature sciences (e.g., biology) began this way and still devote considerable attention to description. Rozin has argued that social psychologists, because of their status anxiety, have too quickly scanted important phenomena in need of basic descriptive work to build impressive formal models of less important phenomena. Cultural psychologists, too, may face the same temptation.

Causal Claims

Many studies attempt to be descriptive *and* make some form of causal claim. Obviously, in planning a study, it is extremely important first to think through what these causal claims might be. They often are of two kinds: (1) Culture 1 has syndrome X, whereas Culture 2 has syndrome Y because of reason R or (2) cultures differ in some local domain D, and these differences derive from some greater underlying difference in major cultural syndromes. Causal claim (1) tends to be more rare among cultural psychologists, so discussion of it is temporarily postponed.

Subquestion 1: “What Is the Cultural Dimension Driving My Differences?”

Claim: Differences in Local Domain D Come from Deeper Differences in Underlying Syndromes X or Y

This type of causal claim often gets made more or less implicitly. Examples of this type of claim might include the following: Japanese and

American conflict resolution styles derive from underlying differences in individualism versus collectivism; or East–West differences in approach versus avoidance motivation derive from more general differences in independence versus interdependence; or Korean versus Canadian differences in leadership style derive from underlying differences in holistic versus analytic thinking style; or Southern and Northern U.S. politeness patterns differ because of the presence or absence of a culture of honor; and so on. These studies are “causal” (rather than “merely” descriptive) in that the measured outcome variable does *not* tautologically derive from the definitions of the deeper cultural syndromes.

A crucial methodological issue involves the identification of the underlying dimension. At times, these claims can seem to derive from what Rosnow and Rosenthal (2002, p. 17) call the “principle of the drunkard’s search.” The name comes from an old joke about a man who has left the bar and is looking for his keys under the lamppost. He knows that the keys probably are not there, but that is where the light is good, so that is where he looks. A potential pitfall for cultural researchers is to look for the underlying causal dimension for a given phenomenon in a place where the light is already shining and the territory is well illuminated.

To continue the analogy, researchers such as Triandis, Hofstede, Markus, Kitayama, Bond, and others have shined a bright light on the cultural syndromes of independence versus interdependence or individualism versus collectivism. Thanks to their work, we know a great deal about these syndromes, and it has become a very salient way to describe cultures. However, there is a methodological problem if one relies too much on this salient individualism–collectivism difference for causal explanations. For example, one might make the following causal claims: Collectivist cultures tend to have inhibitory display rules, to downplay emotionality, to experience more negative affect, to have lower self-esteem and are more avoidance oriented than individualist cultures, which are more expressive, show higher positive affect and self-esteem, and are more approach oriented.

These may all be true, but two methodological issues should give us pause. The first is that cultures differ on any number of dimensions, in addition to the individualist–collectivist differ-

ence. China and the United States differ, for example, not just on individualism–collectivism but also on how tight versus loose they are, how fatalistic, how egalitarian, how religious, how ethnically homogenous, and so on (as well as on many “noncultural” demographic factors—a topic to be addressed later). A general readiness to attribute a difference between an Eastern and a Western culture to individualism–collectivism reflects a tendency to rely (and overrely) on this single well-explored dimension, instead of on many other underlying cultural dimensions that may be causally relevant.

Second, consider that much, though certainly not all, of the individualism–collectivism work has gone in the East–West direction, sampling countries from North America versus East or South Asia. Imagine instead what might have happened if the work had gone in the North–South direction, sampling countries from North America versus South and Central America. A number of our conclusions about the way collectivist cultures are and the way individualist cultures are might be reversed. We might conclude, for example, that collectivist cultures are happier (controlling for income effects), express more affect and assign greater significance to emotion, are more likely to think love should override pragmatic concerns in getting married, are more extroverted, and so on, compared to individualist cultures. The bias in how we have sampled individualist and collectivist cultures has led to certain conclusions about the way individualist and collectivist cultures “generally” are, and these conclusions might be reversed had researchers taken Latin American cultures as their collectivistic prototype rather than Asia.

There are at least two ways to think about what sorts of patterns different cultural syndromes give rise to, and these have very different implications for our methodologies. One way is to think in terms of “necessary” or “contingent” (probabilistic) facts (terms borrowed from the historian Fernand Braudel, 1980). In the search for necessary or contingent facts, we would look for the cultural syndromes that either necessarily or probably lead to certain types of behavior patterns. For example, individualist cultures tend to have more gender equality than collectivist cultures, because the sanctity of the person in such individualist cultures overrides his or her ascribed status or social roles. Or collectivist cultures use

shame as a socializing tool, whereas individualist cultures are more likely to use guilt, because shame involves caring about others' approval, whereas guilt involves self-judgment and needs no audience. In research focused on necessary or probabilistic facts, a diverse sample of cultures is needed so that one can avoid the sampling biases of the type described earlier. In terms of methodology, one may have to sacrifice depth in the name of breadth, gathering data from as many cultures as is feasible, and glossing over the particularities of any one culture.

A second way to think about cultures is in terms of multiple equilibrium states. Although acknowledging that probabilistic facts exist, this way of thinking about culture would focus more on how the pieces of culture fit together in a rough equilibrium in a particular context. In this is also an implicit acknowledgment that many different equilibria might exist. People's behavior depends on the behavior of others around them, and as game theorists have noted, this mutual interdependence leads to multiple equilibria. Some cultures may be at one equilibrium point, others may be at another. (Research in this tradition would be the search for "conditioned facts" in Braudel's [1980] terms).

This statement of multiple equilibria recognizes the fact that there is more than one way to be a collectivist culture, and more than one way to be an individualist culture, for example. And an emphasis in this style of research, then, is to focus on meaning systems and the ways they make the parts of a given culture fit together. Breadth of cultures may be sacrificed for depth of understanding particular cultures. The research of Kitayama; Heine; and Markus and Hamedani (see Chapters 6, 29, and 1, respectively) is a classic example here. In an extensive series of experimental and questionnaires studies, they have elaborated on how the interdependent selfways of Japanese culture get manifested in phenomena such as the pursuit of interpersonal harmony; habits of self-criticism that produce a persistent drive for self-improvement, so that one can meet group standards; the giving of interpersonal sympathy and its role in supporting and enabling self-criticism; the *intrapersonal* realization of sympathy, so that one can also give sympathy to the self one is criticizing; and the treatment of the self as a social object whose actions, and even whose preferences, must situate oneself with

respect to the group. The point in this work is not necessarily to generalize the behavior patterns of North American and Japanese cultures to other cultures. Rather, the work is an exploration of different self-sustaining meaning systems, and this approach to research dictates a methodology that is more focused and less interested in how "probabilistic" facts play out across cultures.

One can imagine a different line of comparative research that examines Latin American and North American cultures, focusing on how interdependent Latino selfways get manifested in the normative expectation that one experience and express positive emotion (Diener & Suh, 2003; Diener & Tov, Chapter 28, this volume); the relational nature of this positive expression of emotion in conveying warmth; the way such emotionality suffuses both work and life (in contrast to the "Protestant relational ideology" that separates the "social-emotional" from the "task focus" relationship; Sanchez-Burks, 2002, 2004; Sanchez-Burks & Lee, Chapter 14, this volume); the cultural script of *simpatia* that promotes harmony through good feelings, congeniality, and charm (Triandis, Lisansky, & Betancourt, 1984); the faith in the most "irrational" of all positive emotions, romantic love (Levine, Sato, Hashimoto, & Verma, 1995; Franiuk, Cohen, & Pomerantz, 2002; cf. Hatfield, Rapson, & Martel, Chapter 31, this volume); and so on. Understanding the importance of harmony and the role of emotion is central in understanding both Asian and Latin American culture, but their roles seem to play out very differently in the two cultural contexts.

Subquestion 2: "Are My Cultural Effects Driven More by Things That Are 'in the Head,' by Things 'out in the World,' or by Some Combination of Both? If So, How Should I Measure Such Effects?"

Causality, Mind-Sets, Individual Differences, and Situations

One of the previously discussed methodological problems involves how one can impute causality (in the search for either "probabilistic facts" or "conditioned facts") and where one should locate it. Four approaches to this problem are discussed below, and as will be seen, conceptual and methodological issues tend to be tethered together here.

SOCIAL-COGNITIVE APPROACHES

One way to argue that a particular cultural “trait” leads to a particular behavior is to prime the mind-set that goes with that “trait” and examine its effect on the behavior of interest (Oyserman, Kimmelmeier, & Coon, 2002; Oyserman, Coon, & Kimmelmeier, 2002; Oyserman & Lee, Chapter 10, this volume).¹ In the area of individualism and collectivism, such work has been done through clever manipulations that ask respondents to think about the ways they are similar to family and friends (collectivist prime) versus different from them (individualist prime; Trafimow, Triandis, & Goto, 1991) or that prime the “we” concept (collectivist) versus the “I” concept (individualist) by having people circle the *we*'s or the *I*'s in a supposedly unrelated reading assignment (Gardner, Gabriel, & Lee, 1999). These priming exercises put people in a certain frame of mind, so that the experimental session simulates what it is like to have interdependent (or independent) thoughts either chronically accessible to an individual or chronically activated by different situations.

Work in this vein has suggested that priming social interdependence, for example, makes both Westerners and Asians more generous in their social comparisons (Stapel & Koomen, 2001; White, Lehman, & Cohen, 2006), more prevention focused in thinking about their goals (Lee, Aaker, & Gardner, 2000), and (for Westerners at least) more holistic in their thinking styles (Kuhnen, Hannover, & Schubert, 2001; Kuhnen & Oyserman, 2002). These findings parallel the same effects that are found when (unprimed) Asians and North Americans are compared, suggesting that social interdependence *can* produce such differences in principle and is a *plausible* explanation for why such differences arise in these cases.

The *manipulation* of the collectivist or individualist mind-set gives researchers tremendous help in establishing causality, because experimental manipulation is the only procedure that can indisputably establish cause. However, there are still some issues to sort through. First, such work does not establish that the chronic differences between cultures are in fact driven by the variable examined in the experiment, rather than by some other (unexamined) variable. To illustrate this point with an absurd example, Asian Americans have generally been found to be less emotionally expressive than

European Americans. Imagine now that one might reverse this effect by giving Asian Americans an arousal-inducing hormone and giving European Americans an arousal-reducing hormone. Such hormones would probably override any culture main effect: The arousal-inducing hormone would lead both groups to be more expressive, whereas the arousal-reducing hormone would lead both groups to be less expressive. However, regardless of the manipulation's success, it obviously does *not* follow that chronic Asian American versus European American expressiveness differences are due to hormonal differences.

Second, this technique, by itself, cannot overcome the problems that come from sampling bias described earlier. For example, one may find that an interdependence prime makes Asian Americans less expressive of emotions. However, if one had drawn a sample of Latinos instead of Asian Americans, one might find that an interdependence prime makes them more expressive of emotions. The priming technique thus deals with causality *in a particular context*. One may be dealing with conditioned facts, such that what interdependence “causes” in one context may not be what it “causes” in another. Nevertheless, the manipulation of a mind-set through priming can make a powerful argument about causality in the groups under study, particularly when such priming evidence converges with evidence gained from one of the other approaches described below.

INDIVIDUAL DIFFERENCES

One can also study culture as a more traditional personality researcher might. Thus, a complementary method for dealing with issues of causation involves the statistical technique of mediation, using measurements that look for individual differences in how much people have internalized the cultural syndrome under study.² Respondents from Culture A and Culture B differ in their behavior in some domain *D* and one wants to attribute this to an underlying cultural syndrome *X* (and it is not simply a tautology to say that differences in domain *D* derive from differences in *X*). For example, Japanese and Canadian styles of handling conflict differ, and a researcher wants to attribute this difference to the greater individualism of Canadians. To use the individual-difference method, one would measure how individualis-

tic or collectivistic a participant is, then use this individual-difference variable as a potential mediator of the cross-cultural difference. The usual testing of mediation is applied. First, one would demonstrate that the Japanese are, for example, more indirect in handling conflict than are Canadians. Second, one would show that (1) Japanese individuals have internalized collectivistic norms more than Canadians have, and (2) individual differences in this norm internalization predict individual differences in handling conflicts. At the third step, one enters both the dummy variable of culture (Japan vs. Canada) and the individual difference measure of internalized collectivism, and shows that whereas the individual-difference variable remains a significant predictor, the effect of the dummy variable is significantly lowered. Ideally, under this approach, the effect of the dummy variable would disappear completely to zero.³

Note again, however, that this does *not* solve the problem of biased sampling described earlier. Suppose, for example, that instead of Canadian and Japanese participants, the researcher had sampled, say, French and Israeli participants for the individualistic and collectivistic groups, respectively. Suppose further that the researcher found that Israelis were more direct in handling conflicts and were indeed more collectivistic. Suppose, finally, that among the French, and particularly among the Israelis, a blunt directness implied interpersonal engagement and respect, whereas indirectness implied a certain standoffishness or guardedness. One might then run the same mediation test and come to conclusions opposite those of the researcher who used the Canadian and Japanese sample and ran the same analysis.

Again, the technique also does not solve the problem of excluding other cultural syndromes. In the Canada–Japan study, for example, one might show that collectivism mediated an effect, but one could not rule out other variables that may have made Japanese participants prefer indirectness (a dialectic thinking style, a greater tolerance for ambiguity, greater deference to authority, etc.), unless one had also measured those other variables and shown they were unimportant. Every correlational analysis always has a third variable problem.

However, the mediational analysis does put the claim on firmer ground. Although it does not rule out the possibility that other variables may be important or that results would differ if

other cultures had been picked, it does make more *plausible* the claim that the difference between these two cultures is driven by differences in the internalization of an underlying collectivist or individualist orientation.

Furthermore, this method has the advantage of explicitly considering individual differences. Not all people are indoctrinated in a culture to the same degree. Not everyone believes or buys into the indoctrination to the same extent. Not everyone will be temperamentally suited to carry out cultural imperatives, even if they buy into them (Rozin, 2003). (Think of a temperamentally anxious person in a culture of honor, or a temperamentally introverted person in a culture whose practices, norms, and values require extraversion.) Additionally, not all subgroups within a culture adhere to the dominant culture's values, especially in ethnically and religiously heterogeneous countries. And even within ethnically or religiously homogenous societies, cultural knowledge is often distributed in a specialized fashion to some people who occupy certain roles and not others. Linton (1936, pp. 272–273) referred to cultural elements shared by only certain groups of people as “specialties” or “alternatives,” as distinguished from “universals,” which are known to all members of a culture. More recently Medin and Atran (2004) and others have explored the idea of distributed culture, with their work on environmental knowledge among the Maya, Q'eqchi', and Ladinos in Central America (Medin, Unsworth, & Hirschfield, Chapter 25, this volume).

INDIVIDUAL-DIFFERENCE MEDIATION ISSUES

Some additional major methodological issues arise, however, with this individual-differences approach—some of which are practical, whereas others are theoretical. These issues are not so much problems as they are challenges for developing a solid and more complete approach to the study of culture.

1. One of the practical issues is one that concerns all mediational analyses; that is, the mediator needs to be measured with some degree of reliability and validity. At present, mediators are usually measured with questionnaires (e.g., an individualism–collectivism scale; Smith & Bond, 2003). However, as is discussed in the section on operationalization, questionnaires are very often underwhelming

in their ability to detect cross-cultural differences. This is *not* per se an argument against mediational analyses. It is simply a reason why questionnaires may not be terribly useful as mediators.

In principle, there is no reason why mediators have to be measured via questionnaires. As long as they are valid, behavioral samples, performance on engaging tasks, or any other measure may serve as a mediator and stand in for the underlying construct. If researchers want to take the individual-difference perspective seriously, it will be useful to develop a repertoire of such nonquestionnaire measures that have demonstrated validity and *are practical to use* as mediating variables (Spencer, Zanna, & Fong, 2005).

2. The theoretical issues with the mediation method are different and quite interesting; by adopting the individual-difference mediation methodology, one is implicitly adopting a certain view of culture. This view locates culture within the individual. Beliefs are held by individuals. Behaviors are done by individuals. Affect is felt by individuals. Cognitions are thought by individuals (Bond, 2002). Whereas this is *prima facie* true, it does miss out on some things that some cultural psychologists would like to consider “cultural” and worthy of study (Fiske, 2002; Miller, 2002). More specifically, it can “reduce” culture to an individual-difference, inside-the-head variable that neglects how situations, practices, and institutional arrangements “afford” certain types of behavior, pulling for one pattern of thoughts and actions rather than another.

SITUATIONAL–STRUCTURAL APPROACH

A situational–structural approach that actually measures affordances that pull for a certain type of behavior—rather than merely asserting that such affordances exist—can require some creative thinking. However, such studies may help clarify why an individual-difference “reductionist” account will be necessarily incomplete. As one example of an interesting and creative situational approach, Kitayama, Markus, Matsumoto, and Norasakkunkit (1997; see also Morling, Kitayama, & Miyamoto, 2002) developed a method of “situation sampling” in which respondents were asked to generate as many situations as they could in which their own self-esteem either increased or decreased. Kitayama and colleagues

(1997) then sampled the situations generated by American and Japanese respondents, and presented them to others for ratings. American raters were more likely than Japanese raters to believe that their self-esteem would go up in the success situations and less likely to think their self-esteem would go down in the failure situations. But perhaps more importantly, the success situations generated by Americans were judged by both Japanese and Americans to be more affirming than the success situations generated by the Japanese, and the failure situations generated by the Japanese were judged to be more deflating than the failure situations generated by Americans. *If* one trusts the “situation sample” to reflect roughly the situations encountered in real life, then the argument can be made that American versus Japanese differences in self-enhancement (vs. self-criticism) at least partially derive from the differences in situations that Americans and Japanese encounter in day-to-day living. (The assumption of a perfect correspondence between the frequency of situations in “real life” and the frequency of situations generated and sampled in an experimental study is clearly untenable. However, it does *not* seem untenable that there is at least a positive correlation between the frequency of situations generated in the lab and situations encountered in real life.)

Another situational approach might drop the issue of “sampling” altogether and attempt to examine in the lab how “prototypical” situations from culture A and “prototypical” situations from culture B will each lead to different sorts of behavior. This too can be a useful way of demonstrating how situations from one culture or another afford different types of behavior. The predictions might involve (1) main effects (e.g., the “prototypical” situation of culture A leads to greater feelings of self-efficacy than that of culture B) and (2) interactions of the sort Morling et al. (2002) found (namely, routinely encountering the prototypical situation helps shape the person such that he or she becomes well-attuned to the affordances and practiced at the culturally appropriate ways of responding. Thus, there may be an interaction such that the prototypical situation of culture A leads to greater feelings of self-efficacy—and this is true *especially* for members of culture A). The disadvantages here are that (1) situations from one culture may not “translate” well to another culture (a point that is discussed later) and (2) the argument

that a situation is prototypical in culture A must be asserted (rather than established through either observations or some technique similar to Kitayama's).⁴

"More" sociological forces also play a role in producing cultural differences (the word *more* is used here to indicate that there is no firm demarcation between where situations that are the purview of psychologists end and where structural forces that are the purview of sociologists begin). Yamagishi (1986, 1988; Yamagishi & Cook, 1993) and others, for example, have produced laboratory experiments that show in microcosm how "structural" factors—such as the presence or absence of a sanctioning system that punishes cheaters—shape people's behavior. In examining the "free rider" problem in which people do not contribute to public goods from which they benefit, Yamagishi (1988) contrasts two approaches: a cultural-individualistic approach and a cultural-institutional approach. The cultural-individualistic approach argues that behavior follows from internal values, such that collectivists do not free ride because they value contributing to the group. The cultural-institutional approach argues that behavior follows from the cultural institutions that have been established to create a certain type of behavior, such that collectivists do not free ride because systems of "mutual monitoring and sanctioning" are commonly established in collectivist cultures (more so than in individualist ones).

The explanations are not mutually exclusive. Thus, people with certain values are more likely to support certain types of institutions; conversely, certain institutions out in the world are more likely to socialize people to certain sorts of values. However, one of Yamagishi's contributions has been to take culture out of people's heads and show how important institutional forces are in this loop between individuals' values and the institutions that create (and are created by) them. More specifically, Yamagishi's experiments have (1) provided evidence for the cultural-institutional approach by showing how opportunities to develop sanctioning systems that punish cheaters and various systems of exchange affect people's decisions to cooperate or to free ride on the group; and (2) have provided evidence *against* the cultural-individualistic approach by showing that Japanese subjects are more likely than American subjects to exit from groups in which

there is no system to monitor and punish cheaters.

Finally, returning to the point that psychological and sociological approaches are intertwined, it is not always clear how one might draw a line between "situational" and "structural." Perhaps the most famous example of this is Milgram's (1974) 18 replications of the obedience experiment, which demonstrated the incredible power of situations and also served as an allegory for the structural forces in the modern state that enable genocides. The lessons of Milgram (make authority immediate and omnipresent, create distance between victim and victimizer, and allow people to shift responsibility for their actions elsewhere) are as much about macro-level sociological issues as they are about micro-level psychological forces in the immediate situation. Milgram himself viewed his obedience studies as preparation for a long-term project on "German character" (Blass, 2004, p. 65). The situational-structural variables were so important, however, that the cross-cultural project never made it out of New Haven, Connecticut.

The results of the studies discussed here suggest plausible arguments for ways in which cultural differences are not located solely within individuals but within practices, situations, collective representations, and institutional arrangements that afford certain types of behavior, enforce certain norms, or prime certain thoughts, and are more routinely encountered in one culture than another. Analyses that measure culture as an individual-difference variable "within the head" would be very usefully complemented by an approach "outside the head" that examined cultural practices, with the goal being a cultural psychology that investigates how culture and psyche "make each other up" or co-create each other (Kitayama & Markus, 1999; Markus & Hamedani, Chapter 1, this volume; Shweder, 1990; Adams & Markus, 2004).

Person × Situation × Culture Interactions/ Cultural Syndromes

A final note should be added about locating causation not just in persons or in situations but in person × situation interactions. Mischel, Mendoza-Denton, Shoda, and colleagues have discussed the notion of "behavioral signatures," or characteristic individual differences that emerge within particular situations (per-

son \times situation interactions; Mendoza-Denton & Mischel, Chapter 7, this volume; Mischel & Shoda, 1995). When one set of “behavioral signatures” characterizes many people within one culture but not another, it may then be helpful to think about Culture \times Person \times Situation interactions. This way of thinking is, in fact, consonant with Triandis’s (1994) approach of discussing cultural syndromes. Such syndromes are not simple traits or behaviors, but are more like a *conglomeration* of traits and behaviors that cohere together meaningfully for people in a culture—even if they do not cohere together for people outside the culture (Cohen, 2001; Nisbett, 2005). Cultural syndromes and within-culture variability create the characteristic behavioral signatures of culture \times person \times situation interactions.

One example of this involves recent work on the cultural syndrome of honor. In some (though not all) honor groups, the syndrome of honor embraces (1) an ethic of bravery, in which one should be ready to commit violence to protect oneself if assaulted or one’s reputation if insulted; and (2) an ethic of virtue, in which one is obliged to adhere to a moral code that demands prosocial reciprocity, trustworthiness, and so on. In most nonhonor cultures, virtue and violence do *not* go together; in fact, in most nonhonor cultures, a morally upright person would be both virtuous in his or her trustworthiness and altruism and slow to use violence. Experiments by Leung and Cohen (2007) with participants from two honor groups (U.S. Southerners and Latinos) and two nonhonor groups (Asian Americans and northern Anglo Americans) support this point. In brief, in Leung and Cohen (2007), it was those Asian Americans and northern Anglos who most eschewed honor-related violence who were (1) most helpful toward a confederate who had previously done them a favor and (2) least likely to cheat in an experimental task to win money. On the other hand, for those who came from a Southern U.S. or Latino culture of honor, it was those who *most* endorsed honor-related violence who also were the most helpful to a confederate and the least likely to cheat. Thus, among members of honor cultures, there was a characteristic “behavioral signature” defined by the syndrome of honor that demanded both a willingness to use violence to defend oneself and an altruistic desire to do good by being helpful and trustworthy. Among members of nonhonor cultures, a systematic but

very different behavioral signature emerged, with the most pacifistic also being the most altruistic. A culture with a syndrome of honor creates one sort of person \times situation interactions; one without such a syndrome creates a very different sort of person \times situation interactions.

METHODS AND APPROACHES

Four approaches to culture have been noted thus far. An individual-differences approach may use experiments or, more commonly, questionnaires, but it will always include some measure of individual differences that is supposed to mediate the cultural effects. Social-cognitive approaches have thus far embraced the methodology of priming to simulate a certain cultural mind-set and then examine the consequences of holding that mind-set. Situation-structural approaches push this back one step further to look for the sorts of situations or structures that exist out in the world that channel or afford certain sorts of behavior; such an approach generally has pushed psychologists toward experimentation. A syndrome approach generally concentrates on the many ways a cultural theme manifests itself in a culture; such an approach favors an eclectic use of methods and may embrace both individual differences, situational-structural approaches, and their interaction.

In summary, although methodologies and theoretical approaches are not perfectly correlated, different methodologies seem generally to flow from different views of culture. And a researcher who unthinkingly adopts a certain methodology also is usually implicitly adopting a certain view of culture. The question is not which approach and method is better, but when should each approach be used. No matter what approach one starts with, it seems reasonable to assume that situations foster certain sorts of mind-sets, and certain mind-sets create certain situations (or make people construe situations a certain way). Situations and social structures create certain habits in people that shape their personalities; and people in turn create or re-create situations and structures that make sense to them. Furthermore, situations and persons interact in ways that may be defined by cultural syndromes, and these patterns of behavior or behavioral signatures may in turn reinforce (or sometimes change) the prevailing syndromes. And, within any culture,

individual differences are guaranteed by differences in temperament, unique socialization experiences, and the existence of various “niches” within a culture that allow for various “types” of people to coexist within that cultural system (Cohen, 2001; Cooter, 1997; Konner, Chapter 4, this volume). The mix of persons within a system creates the niches, which in turn provide space for various “types” of people. Thus, taking a dynamic view of culture ultimately means we need to think from several approaches and, consequently, use a diverse set of methods.

If one were to attempt to build some grand model with individual differences, situations, institutional structures, social-cognitive constructs, and cultural syndromes, the result almost surely would have causal arrows going in all directions. The trick is that (1) these arrows would not be equally strong, and (2) the strength of the arrows would probably vary across topics of study. We need to think about an issue from several different approaches, pick what we think is the most useful place to start, then see where to go from there.

Subquestion 3: “What Ecological, Economic, or Historical Circumstances Caused the Cultural Difference to Emerge in the First Place?”

The issue of causality also arises when we ask why the cultures under study are different in the first place. Obviously, part of the proximal answer has to do with the way individual psyches help co-create the culture through their behaviors, both individually and collectively (see Markus & Hamedani, Chapter 1, this volume). Understanding this process is one of the key goals of cultural psychology. However, sometimes we are also interested in the distal question of why certain cultural patterns arose in the first place. What were the ecological, economic, or historical factors that gave rise to the cultural pattern?

For example, Norenzayan, Choi, and Peng (Chapter 22, this volume; Nisbett, 2004; Nisbett, Chapter 35, this volume) have argued that a holistic thinking style developed in the East out of an environment and ecology that gave rise to large-scale agriculture, an endeavor that requires cooperation and interdependence. This social interdependence in turn gave rise to a holistic way of thinking, in which context and relationships took priority over individual objects and categories. In contrast, they theo-

ricized that an analytic thinking style arose in the West because the ecology of Greece encouraged herding and fishing rather than large-scale agriculture. Such ecological and economic circumstances meant that Greek society was less centralized and more fragmented than Chinese society. Greek social atomism in turn led to an atomistic, analytic mode of thought that concentrated on objects rather than relationships. Furthermore, Greece’s place at the crossroads of the Mediterranean meant that there was a diverse “marketplace of ideas” and a need for formal systems of logic to sort out the good from the bad ideas.

Such ideas about social interdependence leading to more holistic thinking are given plausibility by laboratory experiments that set up these causal arguments in microcosm. For example, they are given plausibility by laboratory experiments showing that priming collectivism or priming individualism leads to more context-dependent or context-independent ways of thinking, respectively (Oyserman & Lee, Chapter 10, this volume; see also van Baaren, Horgan, Chartrand, & Dijkmans, 2004). These experiments make the causal argument somewhat more plausible, but to make a stronger statement about the links between ecology, economy, history, and culture, it is necessary to collect data on the actual ecological, economic, or historical circumstances themselves.

Ecology and Culture

The most famous contemporary example of this is Jared Diamond’s (1999) *Guns, Germs, and Steel*, in which he traces the economic advancement and political dominance of cultures to early climatological and geographic factors that allowed for the domestication of plants and large animals. The development of agriculture in such societies led to surpluses that could sustain larger populations and occupational specialization. Thick population densities and the presence of domesticable animals in Eurasia also led to the development of certain crowd diseases. The germs of these diseases then became the most deadly forces as Eurasians spread across the globe. Diamond’s book draws on the fields of anthropology, linguistics, genetics, and zoology to provide data for his argument.

Obviously, most of us have to be content with more humble undertakings than Dia-

mond's. A few examples of such work empirically linking ecology to culture might include the following: Berry (1979) examined 17 cultures and showed that a culture's rate of conformity was highly correlated with whether its ecology encouraged cooperation (e.g., agricultural societies) or more individualistic activities (e.g., hunting and gathering societies); Henrich et al. (2001) examined 15 small-scale societies to see how fairly they would split a sizable amount of money provided by the experimenter, and they found that 50:50 splits were more likely to come from societies in which people (1) frequently engage in market transactions and (2) can realize big economic gains by cooperating with others outside the family; thus, a society in which the economic activity of whale hunting demands lots of cooperation tends to produce fairer offers than a society in which families are "almost entirely economically independent" of one another (Henrich et al., 2001, p. 76). Vandello and Cohen (1999) examined historical land use patterns of various U.S. states to see how 19th-century agricultural patterns predicted contemporary measures of individualism and collectivism, and so on.

Note that most of the examples above come from *cross-sectional* data. Thus, it is tempting to assume that ecological and economic factors preceded the development of cultural traits. However, without longitudinal data, one cannot rule out the possibility that the causation goes the other way. That is, one cannot rule out the possibility that more atomistic, less cooperative cultures gave rise to economies that did not require individual families to work with one another, whereas more cooperative cultures could take advantage of their synergy to create economic systems with more integration. To believe that ecology determines and *must necessarily* lead to certain economic and cultural arrangements is to assume that human cultures (1) do not alter their ecology, (2) do not move and self-select their ecological niches, and (3) always make the best use of their local ecology and thus inevitably end up at rational, adaptive economic and cultural arrangements. (If item 1, 2, or 3 is violated, then human choices and the cultural influences on them have entered the picture.) Assuming cultural arrangements are rational adaptations to the environment is a good place to start, but it is an assumption nonetheless.

ASSUMPTION NO. 1

In searching for a causal explanation, the usual assumption is that a cultural pattern is a certain way because it is functional or in some way adaptive for the culture. Again, this is probably a decent starting point in guiding research, but there are reasons to be wary. The first is that contemporary cultural patterns are not necessarily adapted to *current* environmental or ecological circumstances. Thus: the culture of honor may have arisen in the frontier South and West, but it may continue on long after the frontier has disappeared. High fertility rates that may have been adaptive in some agricultural settings persist after societies have become urbanized, child mortality rates have lessened, and children have become economic liabilities rather than assets (Triandis, 1994). Dysfunctional patterns of distrust, corruption, and "amoral familism" may persist even after autocratic governments have been displaced, and these patterns may undermine democracy and effective government (Putnam, 1993). And so on. Just as biological adaptations (e.g., a taste for fat and sugar) are no longer "adaptive" in places such as the United States, where people are surrounded by fat and sugar, so too are some cultural adaptations. A methodology that searches for the contemporary reasons why a cultural pattern is adaptive may come up empty-handed or worse; it may come up with a fallacious "just so" story for the current behavior.

There are at least some constraints in evolutionary psychology, because genes change only slowly (see also Atran, Chapter 17; Cole & Hatano, Chapter 5; Konner, Chapter 4; Li, Chapter 21; and Newson, Richerson, & Boyd, Chapter 18, all this volume). Think about the classic food preference example just given. People like McDonald's, but we know that a taste for McDonald's is not an adaptation, because McDonald's has only recently come into existence. Instead, our distant ancestors craved fats, sugars, and salts, and McDonald's has merely taken advantage of that ancestral adaptation (Symons, 1992). Cultural psychologists have a more difficult time than evolutionary psychologists, because cultures can change relatively rapidly (much more rapidly than genes); thus, cultural psychologists are not as constrained in their thinking about adaptations. It is possible to create many "just so" stories about why a given cultural pattern

might be adaptive, because there is nothing that constrains our theorizing on *when*, *why*, and *in what circumstances* a cultural adaptation might have arisen.

Thus, a cultural pattern may in fact be adapted to current environmental circumstances. Or it may be adapted to any number of historical environmental circumstances. Or it may not be adaptive at all. A functionalist causal explanation may be false in some cases. Edgerton (1992) in particular has challenged what he calls “the myth of cultural adaptation.” He asserts that cultural practices are rarely optimally functional, occasionally quite dysfunctional, and often unequal in the benefits they confer to different members of the society. Human culture may be as much a product of greed, xenophobia, sexism, shortsightedness, and irrationality, as our positive human qualities (see also Diamond, 2005). As much as possible, it makes sense to attempt to verify our general assumptions about adaptiveness and substantiate them in particular cases. Furthermore, we need to be precise about what *adaptive* means. Even when every individual is acting adaptively or rationally, that does not mean the overall cultural pattern is functional. An obvious example here is when the situation is structured as a “prisoner’s dilemma” or a “tragedy of the commons.” Every individual may behave rationally and adaptively, but the collective result is the worst possible, least functional outcome; and this worst possible outcome can also be a relatively stable equilibrium state.

Sources of Data

Researchers who study the links between ecologies, economies, history, and culture often need to work with archival data. Such data are abundant, though not always easy to find. Modern states are obsessive record keepers; however, depending on the topic, the records can vary in their quality and the amount of work needed to turn these records into manageable data. A great source for this data is data sets archived at the Inter-University Consortium for Political and Social Research (ICPSR; www.icpsr.umich.edu/). The Human Relations Area Files are available electronically and, as of 2004, had a searchable database with over 350,000 pages of information (www.yale.edu/hraf/). Other databases, such as the Standard Cross-Cultural Sample of 186 so-

cieties (eclectic.ss.uci.edu/~drwhite/worldcul/world.htm), have been developed to avoid “Galton’s problem” (the nonindependence of cultures due to either diffusion or a common history; Murdock & White, 2006). (Galton’s “problem,” of course, becomes an opportunity for researchers who study cultural diffusion and transmission; see Guglielmino, Viganotti, Hewlett, & Cavalli-Sforza, 1995; Pagel & Mace, 2004.) Still other collections should come online in the future.

Summary

In summary, not all cultural psychologists (particularly those doing the important basic work of description) need to worry about causality. But those who do need to think in terms of equilibriums (rather than, or in addition to, straight correlational thinking). Multiple ways of ordering the world can be meaningful, sensible, and coherent; discovering what these multiple cultural logics are is part of what cultural psychologists do.

Cultural psychologists also need to grapple with the question of where to begin: Social-cognitive, individual-difference, situational-structural, and cultural syndrome or culture \times person \times situation approaches all have something to contribute. Those doing more macro work also need to grapple with issues of gathering the sort of ecological, economic, and historical evidence that produces convincing arguments that go beyond just-so stories.

SAMPLING

The Causation section described how the sampling of cultures can drive our conclusions about what cultural syndrome gives rise to what patterns in particular domains. This section concentrates not on deciding which cultures to examine in our research, but on how we select participants once we have decided on the populations. As will be seen below, issues in sampling implicitly have views of culture built into them.

The issues to consider in thinking about sampling are as follows: What population are we hoping to generalize to, and what sorts of arguments are we trying to make? We first mention the relatively straightforward case of a researcher attempting to estimate a population parameter using a probability sample. We then

deal with the more common case of researchers who do not use probability sampling.

Probability Sampling

In some cases the leap from sample to population can be made reasonably confidently—cases in which probability sampling is used and nonresponse rates are at an acceptably low level. From the populations, one develops a sampling frame (a list of all possible elements that could be included in the study). From the sample frame, one then draws the sample. Under probability sampling, all elements have a known and nonzero chance of being selected. Opinion surveys done with probability sampling are typically conducted by sociologists and political scientists or those working in collaboration with them. To get response rates at 80% or more, these usually have to be done by phone or in person, with multiple callbacks. There are various issues to consider with even very good probability samples (see Schuman & Kalton, 1985). But for the most part, one is on terra firma going from sample to population with most of these studies.

Studies using probability samples are often archived and available for secondary analysis by psychologists. This represents an excellent opportunity for those who study research questions related to the topics of such studies. However, because the secondary researcher was not the original investigator on the study, and the original investigator was probably not a cultural psychologist, one often has to make do with less than optimal questions. Large-scale surveys are extremely expensive, and the number of questions quite limited because time is at such a premium on them. Thus, psychologists going through survey archives may find that a typical survey does not cover a topic at the depths to which they are accustomed. However, the potential benefits of being able to find such data and use it in conjunction with data from a convenience sample (e.g., that gathered from the introductory psychology pool) are tremendous. Merely having a large N gathered from a convenience sample does not give generalizability; only a probability sample can give that. (This lesson was learned by the *Literary Digest* in the U.S. election of 1936. In a spectacularly wrong forecast, the *Digest* confidently predicted Landon would beat Roosevelt after getting 2.4 million survey respondents from across the country. Among other prob-

lems, however, the *Digest* constructed its sampling frame from sources such as telephone books, and car registration and country club membership lists. The problem was that in 1936, car ownership was not widespread, only one in four households had a telephone, and assuredly a smaller proportion than that belonged to country clubs. Of course, right now, a phone survey that uses random digit dialing (to get around the problem of unlisted phone numbers and cell phones) can get a pretty fair representation of the U.S. population. But that is *not* necessarily true in many countries, where telephones are far less common.

Good sources of large-scale survey data can be found at ICPSR, which houses data from sources such as World Values Surveys, National Opinion Research Center's General Social Survey (and its international counterparts), and the Institute for Social Research's National Election Study. Surveys such as these have a large N in any given year, and some of the same questions are asked from year to year. With such a large N , it is possible to investigate subcultures or systematic within-culture variation by socioeconomic status (SES), region, and so on; also, assuming one can reasonably aggregate across years, one can get a meaningful size N for small groups that do not show up in sufficient numbers in any given year. (For example, at 2% of the U.S. population, there will be 20 Muslims and 20 Jews in a survey of 1,000 respondents. Aggregating over, say, 10 years would give a more substantial 200 each.) Additionally, the repetition of questions in different years allows one to track changes over time, separate out generation effects from age effects, and, if the study is a panel study, follow the same people longitudinally over time.

Subquestions 1 and 2: "About What Population Can I Sensibly Generalize, and How Do I Think about What Is 'Culture' and What Is 'Confound' When I Pick My Sample?"

Nonprobability Sampling and Statements of Generalization: Too Big or Too Small?

For most cultural psychologists, secondary analysis of survey data will be used only as a complement to their main line of work. In the section on causation, the unavoidable problem was that no correlational study can prove causation. In the sampling section, the unavoidable problem is that no study without probabil-

ity sampling can generate a safe generalization, because no one knows who exactly the study's sample represents.

Generalization is an inherent part of our work, however, as described in the following sections. How then do we deal with the unsolvable problem? Our sampling approaches are designed to be *suggestive* of some types of generalization, and a few imperfect approaches to sampling are described as a way to make studies more suggestive rather than less suggestive.

From Sample to Population and Vice Versa

In most noncultural psychology studies, the population is usually implicitly hypothesized to be all human beings, the sampling frame is the list of sophomores who have signed up for Psychology 1 this year, and the sample is the 80% of those who actually show up at the lab to participate in our study. In most culture studies, the population-to-sample link is only somewhat better. The population might implicitly be something like the 2.5 billion members of Eastern civilization and the billion members of Western civilization. The sampling frame is the Asian Americans and European Americans in the Psychology 1 pool, and the sample is those who show up. The absurdity of going "too big" in one's generalizations is obvious here.

Consider also the opposite problem of going "too small" and the paralysis it leads to in either selecting a sample or drawing conclusions. A researcher considers a study comparing the political cultures of Brazil and Argentina with the United States and Canada. The researcher wants to argue that some result illustrates a difference between the political cultures of Latin American and North American societies. A critic would correctly point out that Latin America is not "monolithic." The South American countries are different than the Central American countries. And within South America, the countries of Brazil and Argentina will be different from, say, Peru and Bolivia. Within Brazil, the states of northern Brazil will be much different than those of southern Brazil. And within southern Brazil, the state of São Paulo will be different from, say, the state of Santa Catarina. And within São Paulo state, the city of São Paulo will be different from those more inland. And within the city of São Paulo, . . . and the regression can go on ad infinitum, until one is thoroughly torn about

where to start the research and then afraid to make any homogenizing statement or generalize past the N specific subjects in the study once it has been completed.

For anyone not using a probability sample, the generalization problem is always there, whether or not it is acknowledged. For example, a researcher studying, say, parent-child socialization might sensibly say that she does not care if her results generalize to other Asian populations or to all Japanese. She may situate her research as examining processes and meanings within upper-middle-class Japanese and American parent-child interactions. That is, she may argue that her research concerns not the "grand" traditions (Eastern vs. Western culture, Buddhism, Confucian thought, etc.) but "local" traditions. (See also Glazer, 2000, on Redfield and Singer's notions of "great" and "little" traditions.) However, unless there was probability sampling, she has in fact no reason to believe her findings apply to other upper-middle-class Japanese and American parents, to other upper-middle-class Japanese and American parents from these particular towns, or even these particular neighborhoods, and so on.

If one wants to talk about one's findings as applicable to groups other than the specific subjects in the study, a generalization is being made. And perhaps more importantly, if one wants to talk about something as "cultural," then one is by definition talking about something shared among some group of people that is usually larger than the particular group of participants in this one study.

It is true that a researcher may not be interested in generalizing to estimate an exact population parameter (e.g., 57% of Japanese middle-class moms do it this way, whereas only 25% of American moms do). However, the researcher is implicitly generalizing whenever he or she describes something as "cultural," because he or she is usually referring to some set of practices and meanings that are either shared, acknowledged, or contested by some group of people (usually larger than the study N).

Sampling Approaches

The limitations of nonprobability samples lead to one of the fundamental paradoxes of cultural psychology. That is, part of cultural psy-

chology's critique of mainstream psychology was that it was studying psychological principles that it claimed were universal, but that in fact were only tested on and perhaps true of only a small subsection of the population. Instead of a psychology of human nature, we essentially had a discipline that might have been what Shweder (1997, p. 155) would call "Anglo American cultural studies."

The work of cultural psychologists, however, has the same limitation in that it is similarly unclear how we can take findings from our sample and make them more broadly relevant to a study of culture. Given that any sample that is not a probability sample cannot pretend to know to whom the results generalize, how can one sample in a way that still allows one to say something useful about culture—either big-*C* Culture (Chinese culture, American culture, Mexican culture, etc.) or little-*c* culture (the process by which people make and are shaped by their world; Glazer, 2000)?

There are at least four approaches. They do not solve the problem that one cannot generalize past a sample without using probability sampling, and they all have different problems. However, they may all contribute something useful to understanding the way culture works. These four approaches might be called the typicality approach, the just minimal difference approach, the cultural experts approach, and the inversion approach.

TYPICALITY VERSUS THE JUST MINIMAL DIFFERENCE

A researcher is comparing cultures A and B. How should she draw her samples of people or families, or her sample of schools (or whatever her sampling unit is) from group A and B? One principle is to match on "typicality," so that one might compare "typical" groups in culture A with typical groups in culture B rather than having to compare typical groups in culture A with outlier groups in culture B. A competing way might be to match participants from the two cultures on the principle of the "just minimal difference." In the latter approach, one would try to match the samples as closely as possible on all variables, so that the only difference left is the difference in the cultural histories of the two groups. Practically speaking, the samples are made as similar as one can reasonably make them, so that exposure to culture A versus exposure to culture B becomes the *most*

obvious explanation when other obvious but "noncultural" factors have been equated.

The difficulty in the first approach is clear. How does one decide who is "typical"? It is far easier to decide who or what is *atypical* than to decide who is typical. For example, it is reasonably safe to say that a sample from the Upper West Side of Manhattan or Beverly Hills or northern Idaho may not be a "typical" American sample. But who would qualify as typical—a sample of people from Minnesota or Peoria, Illinois, or the ever-popular test market, Columbus, Ohio, with its location at the geographic and political center of the state that is "the epitome of American normalcy" (*Encyclopaedia Britannica*, 2004; Will, 2004a)? It is likely that by *typical* researchers probably mean *not atypical* in many obvious ways. Unless there is some well-established modal group that is statistically quite common or some culturally agreed on prototype, it is likely that *typicality* or not atypical is going to be a subjective call.

The latter approach—the just minimal difference—has an intuitive appeal to psychologists who primarily use controlled experiments. It is an attempt to mimic random assignment by keeping "everything else constant" and just concentrating on the cultural difference of interest. The problem is that there is no real random assignment, so there is no "everything else constant." However, there is also a deeper problem here: This approach implies that one is able to sort out what is the "cultural" factor from what is a confound or an extraneous factor. It is not clear that this is possible or even always desirable (see also Medin et al., Chapter 25, this volume).

One probably does not want to consider *all* differences between two cultural groups as a *cultural* difference (as opposed to an economic difference, ecological difference, demographic difference, etc.).⁵ However, depending on the area of study, the line between what is cultural and what is, say, a confounding demographic factor can get quite blurry. For example, what does it mean for one to control for income when comparing cultural groups that renounce worldly success versus those that embrace it as a sign of the elect? Or what does it mean to control for education in comparing groups that emphasize formal schooling with those that do not? (See Glazer [2000, p. 226] also for similar discussions of preference for rural vs. urban liv-

ing, or family size and structure as both a demographic variable and a “cultural feature par excellence,” etc.). As Adams and Markus (2004) noted, one essential part of the “dynamic construction” approach to culture involves the blurring of the division between what is “culture” and what is “social structure,” because both re-create each other. Some of that “everything else” that one is trying to get rid of may be a defining part of the cultural phenomena.

Then again, maybe not. Thinking about these issues forces a researcher to think about the nature of his or her study: (1) Is the aim to focus narrowly and analytically on a specific, circumscribed cultural practice, so that one can pinpoint its importance? (2) Is the goal to identify this difference as more “cultural,” implying that it expresses some sort of chosen value for the group that will endure even if more “structural” or demographic changes occur? If either (1) or (2) is the aim of the study, that might push one toward a sample based on the “just minimal difference,” so that one can focus in on the practice of interest, keeping at least *some* “other things equal.” Or, for example, is the aim (3) to capture the “Gestalt” of the culture—to examine how the various aspects of the culture fit together and support one another (or clash)? If the latter is true, then that might push one more toward a sample based on some definition of “typicality,” in which it does not make sense to “keep all else equal,” because “all else” is part of what one is trying to study.

In some ways, the answer to the question of whether one wants to focus analytically or to capture a Gestalt is like the answer to the question of whether one wants vanilla or chocolate ice cream. The correct answer is, “Yes, both.” In that case, within a given study one can sample not only widely but also strategically, selecting some of the sampling units based on the principle of “typicality,” and others based on the principle of “just minimal difference.” For example, if one is drawing a sample of, say, 10 schools, one can choose, say, five “typical” schools from each culture, then choose the other five schools with an eye toward matching them as closely as possible, so that one can isolate a particular characteristic of interest. Research budgets often do not allow for such sampling and, in that case, one simply has to determine the most important research goals for the study.

EXPERT SAMPLING VERSUS INVERSION SAMPLING

Expert sampling and inversion sampling represent two opposite approaches. One stacks the deck in favor of finding the cultural difference; the other stacks the deck against it. In expert sampling, one makes no pretense of studying the average group member. Instead, one tries to bring cultural systems into sharp relief by studying cultural “experts,” where “experts” does not mean scholars but rather means the people most immersed in, most competent in, or who most embody a culture in its more “pure” form. Such a study with cultural experts may stand on its own, or it may be a prelude to future studies involving wider populations. For example, in studying reasoning about the natural world, Lopez, Atran, Coley, Medin, and Smith (1997) focused on Itza’ Maya elders who spoke Itza’—clearly an exceptional group, because “the ‘typical’ Itza’ speaks mainly Spanish” (Medin & Atran, 2004, p. 964). Then, once sharp cultural differences have been defined through studies that use expert sampling, subsequent research may go on to study the distribution and transmission of these “expert” ideas across networks within the community. The appeal of expert sampling is obvious and is quite consistent with Kurt Lewin’s directive to “start strong.” However, the drawbacks to this method are obvious as well: (1) It will not always be clear who the “experts” are, or who is most culturally competent (again, it is probably easier to identify who is not an expert or competent) and (2) depending on the size of the gulf between the experts and everybody else, the findings on the expert population may or may not prove useful in generating subsequent research with nonexpert populations.

A different possibility is to do the opposite of expert sampling and sample the subgroups that theoretically would be the *least* likely to produce a cultural difference. There are a few reasons one might do this type of inversion sampling. For example, one might want to strengthen the generalization inference by showing that the cultural difference exists even in extreme cases when the cards are stacked against it. Thus, in studying political culture, if one showed that even the most conservative Canadian province favored socialized medicine more than the most liberal U.S. state, one can make a stronger inference about a more general U.S.–Canada difference. A very different rea-

son to engage in inversion sampling might be to test our understanding of a phenomena by “flipping it on its head,” as Norbert Schwarz would say. Suppose, for example, one were studying differences in fatalism between Country A, which primarily grows a high volatility commodity a, and Country B, which primarily grows relatively stable commodity b. If one wanted to focus in on the connection between commodity volatility and fatalistic practices, it might be useful to include in one’s sample some unusual regions from Country A that grew commodity b, and some unusual regions from Country B that grew commodity a.⁶ In the typical regions of countries A and B, one might show how A’s practices are more fatalistic than B’s; but with the atypical regions, one might strengthen the argument about volatility and fatalism by showing that the effect flips on its head in these atypical regions. This type of sampling has an appeal to experimentally trained cultural psychologists. However, the same limits about claiming causality still apply, because the independent variable (in this case, commodity volatility) was still measured rather than manipulated.

College Student Sampling and Ethnic Group Sampling

Issues in college student sampling and ethnic group sampling are just special cases of the general issues discussed earlier. Nevertheless, they merit greater treatment, because practical considerations (ease of recruitment, ease of standardizing procedures, etc.) make using such samples quite popular.

College Student Samples

Given a desire to create the just minimal difference and the ready convenience of college samples, many researchers have opted (1) to find comparable colleges, then sample college students from various countries or (2) to study college students of different ethnic groups within a single country (see below for more on the latter). In psychology as a whole, somewhere around 80% of research on “normal” adults has used such college student samples (Rosnow & Rosenthal, 2002, p. 14). Within cultural psychology, no one has yet calculated a comparable estimate.

For cultural psychology, there are, of course, the usual hazards of using college student sam-

ples, then hoping to generalize beyond them. However, in cultural psychology, there are additional concerns as well. Within the United States, we have some suggestion of at least some of the ways college students differ from the rest of the population (see Sears, 1986), but such data may or may not be known for other countries. Furthermore, in almost every other place in the world, college students are likely to be an even more rarefied section of the population than they are in the United States, where approximately one in four persons ages 25 to 64 has a university education. By comparison, the number is only half that in places such as the progressive Scandinavian countries, the United Kingdom, and the other countries of the European Union (U.S. Bureau of the Census, 1999, p. 840). In most nations outside Europe, it will be lower still. The researcher trying to create the just minimal difference may wind up comparing a college student elite in the United States with a college student superelite elsewhere. This researcher may be equating on education, but he or she is not equating on social status or life chances. Whether there is an education effect or a social status effect—and on which one it might be more important to equate—is an issue that may vary depending on the research topic (see also Schooler, Chapter 15, this volume).

Many people’s intuitions are that comparing a U.S. elite with a non-U.S. superelite will lessen the chance of finding cultural differences, because “cosmopolitan elites” share certain traits and values across the world (Shweder, 2000). For the researcher hoping to find a cultural difference, this is a good thing, because it means that the confounding factor usually works against the hypothesis rather than for it; thus, it cannot be a valid alternative explanation if differences are found.

However, in any given case, it is an open question whether cosmopolitan elites will be more like each other than are their respective populations. To the extent that one is comparing a Western culture with a non-Western culture *and* to the extent that elite status implies Westernization, the use of college student samples will probably work against the hypothesis. However, it is not clear that either modernization of a country or elite status within a country does actually lead to Westernization (Huntington, 1996). Probably in some countries and in some domains it does, and probably in some countries and in some domains it does not.

This is an empirical question, and we may or may not have the data to settle it for every particular domain of inquiry.

Comparisons between Ethnic Groups and between Countries

To create the “just minimal difference,” some studies examine ethnic groups within a given country as opposed to between countries. For example, one might study Chinese Americans and European Americans rather than people in China and in the United States. There is much to be said for this approach, and, very practically, keeping the study at one location also helps to equate the operational details involved in actually running the study. For example, if one is running a study examining how European Americans and Chinese Americans respond to the loss of face, one can employ the same face-losing procedure with the same experimental confederates. And even when the study is not a high-impact (highly involving) laboratory experiment, a study that involves European Americans and Chinese Americans can use an English questionnaire to avoid translation ambiguities (discussed in the next section) or extraneous effects of language (discussed in Chiu, Leung, & Kwan, Chapter 27, this volume; Norenzayan, Choi, & Peng, Chapter 23, this volume; Perunovic, Ross, & Wilson, 2005; Wang & Ross, Chapter 26, this volume), if such effects are indeed extraneous.

However, if one wants to talk about Chinese culture and American culture, the comparison of European Americans with Chinese Americans minimizes some extraneous differences but creates others. For one thing, if one is using recent immigrants, a whole set of challenges accompanies trying to settle into a new culture. For another thing, even if one does not use recent immigrants, culture will be confounded with majority or minority status in most places in the United States. And as an entirely separate matter, immigrants are likely to be systematically different from their counterparts back home on at least some personality and demographic variables. In some cases, this is fine, because some preexisting differences and some challenges that new immigrants face may work against the hypothesis in question and so cannot be alternative explanations. However, in other cases, it will not always be clear that this is so. Thus, generalizing from Chinese immi-

grants to Chinese culture or generalizing from Chinese culture to Chinese immigrants is not a move that can be taken for granted (Glazer, 2000). Again, more abstractly, it may not be simple to go from the “local” traditions of a particular group in a particular place to the “grand” tradition (e.g., Eastern culture) from which it may have derived (and vice versa for the direction of inference).

*A Novel Sample:
Culture as an Experimentally Primed Variable*

Samplings based on typicality, just minimal differences, expertise, and inversion are four of the multiple ways one might choose to sample. The just minimal difference approach and the inversion approach should be appealing to psychologists who come from an experimental background. However, the fundamental problem is that we cannot get rid of the third-variable problem, because we cannot randomly assign people to culture and consider it a manipulated variable.

There has been at least one ingenious sampling strategy for helping with this problem, though. Hong, Morris, Chiu, and Benet-Martinez (2000; Hong, Wan, Ching, No, & Chiu, Chapter 13, this volume) have done studies in which the sample is made up of bicultural individuals who have been socialized in two cultural traditions (in their research, they have used both residents of Hong Kong and Asian Americans). These bicultural individuals are then randomly assigned to receive an experimental manipulation in which they are primed with either Chinese icons (the Great Wall, a Chinese dragon) or American icons (Marilyn Monroe, the American flag).⁷ In their research, they have, for example, shown that Chinese icons tend to push bicultural individuals toward Eastern, group-centered descriptions of events, whereas American icons tend to push them toward Western, individualistic descriptions. One does not get around the problem that bicultural individuals are a special subset of the population, but one does at least get around the problem of confounding culture with some of the other variables one would like to control. According to one way of thinking, bicultural individuals were a problem to be avoided—they were too tainted by culture A to be a “true” member of culture B, and vice versa. Hong et al.’s important move was to see

working with such individuals as presenting an opportunity to manipulate (at least temporarily) cultural schemas. All sampling techniques are going to be flawed in some way, but as cultural psychology matures, it is likely that more of these clever sampling techniques will be developed as part of the discipline's repertoire.

*Pragmatic Recruiting Concerns:
Our Subjects Select Us*

Whereas the previous sections have dealt mostly with how we select our subjects, a brief note should be added about how our subjects self-select into our studies. Two pragmatic recruiting concerns are (1) advertising culture in our studies and (2) paying participants. The effects of both are unclear, but the theoretical reasons why they may matter await further research.

The issue of how we advertise our studies is relevant both for studies that use community members and those that use psychology department participant pools and have to entice participants to sign up. Any researcher that uses sign-up methods faces the problem of participant self-selection. However, culture studies have an additional concern, in that they sometimes advertise for people of a particular ethnicity. At this point, I am unaware of any research that directly compares data from studies in which culture is explicitly advertised as a factor with those in which it is not. There may in fact be no differences, but it is possible that studies in which culture is advertised (1) are more likely to attract participants who are highly identified with their ethnicity; (2) may prime ethnicity for participants, thus making them more likely to follow cultural norms (Hong et al., 2000); (3) may produce "stereotype threat" effects (Steele, 1997, 1999); (4) may produce more "good subject" effects as participants try to give researchers the desired results; or (5) in an opposite fashion, may elicit more behavior that tries to disconfirm the stereotype, especially if that stereotype is negative. Four out of these five possibilities would exaggerate cultural differences. (Additionally, these effects may become even bigger when a large number of researchers use a participant pool with a small number of subjects who are, say, Asian American. Such a situation may produce "professional ethnics," with the same small

group of Asian Americans being used in culture study after culture study.) If advertising for culture does indeed affect the results, the researcher would probably want to know why, because some of these reasons (particularly items 3–5 from the preceding list) seem artifactual.

Finally, we know something about the distinguishing characteristics of volunteers for research in the United States: Volunteers tend to have higher SES, education, IQ scores, need for approval, are more likely to be female, and so on (Rosnow & Rosenthal, 2002). Much less is known about volunteers in other countries. Particularly when studies are conducted in poorer countries and "volunteers" are paid, one might expect that at least some of these volunteerism biases reverse (e.g., one may get "volunteers" lower in SES and education). How much of a concern this is will probably vary from study to study.

**Sampling Technique(s) Appropriate
to the Research Question**

In summary, cultural psychologists need to take the issue of participant sampling seriously; that is the basis for the field's critique of mainstream psychology as a psychology of relatively elite Western populations. Rarely do cultural psychologists use probability sampling themselves, so it is definitionally unclear to whom our results generalize. Yet various sampling techniques may help us say something useful about either big-C Culture or little-c culture (e.g., typicality sampling vs. just minimal difference sampling, expert sampling vs. inversion sampling, bicultural sampling).

There are inevitably trade-offs in choosing one type of sample or another. Different sampling techniques have implicitly built into them different views of "what culture is." For example, as described earlier, questions of whether one is dealing with the grand traditions or local ones, of how best to keep "everything else equal," or whether one even wants to, are questions that are implicit in how the samples are selected. To make good decisions as researchers and good interpretations as readers, we need to define the research questions precisely, think through the sampling trade-offs we might make, and choose the sampling technique(s) most appropriate for our project.

OPERATIONALIZATION

Once one has thought through these issues, it is time to operationalize the hypothesis with measures of the dependent variable and measures or manipulations of the independent variable. Several excellent guides explore both the art and the science of operationalization (Berry, Poortinga, & Pandey, 1996; Gilbert, Fiske, & Lindzey, 1998; Schuman & Kalton, 1985; Schuman & Presser, 1981; Triandis & Berry, 1980; Triandis, 1994). This chapter can only briefly sketch out a few issues as they apply to culture. For all social scientists, the essential challenge of operationalization is to create variables that are convincing and interpretable. For cultural psychologists, these variables have to be convincing and interpretable when seen through (at least) two different cultural lenses.⁸

Subquestion 1: "Am I Translating My Variable Correctly from One Culture to Another?"

One of the big issues for cultural psychologists is that of "translation," which is loosely defined as making sure one's measures and manipulations are the same across cultures. The issue is obvious when it comes to language, but it also applies to translating situations and observations, as discussed later.

Linguistic Translation

If the study is to be conducted in two or more languages, one must have the materials translated and backtranslated. Thus, a first bilingual may translate materials from Vietnamese to Russian and a second bilingual will translate the materials back from Russian to Vietnamese. One can add a number of different protections, including having multiple bilinguals do the translation, the backtranslation, and reconcile any differences. Furthermore, one can conduct the process iteratively, subjecting the materials to multiple rounds of translation and backtranslation. It sounds straightforward enough, but anyone who has done it knows how difficult and tedious this can be.

A few examples illustrate the importance of slogging through what seem to be even the most tedious of issues. Monolingual English speakers probably think there could be nothing easier than translating the word *is*. But as President Bill Clinton observed in a very different context, "It

depends on what the meaning of the word 'is' is." In Spanish, the word *is* has two forms—*estar*, which is "generally used for temporary properties," and *ser*, which is generally used for permanent ones (Heyman & Diesendruck, 2002, p. 408; Sera et al., 1997). As Heyman and Diesendruck (2002) have shown, these two forms have consequences for attributions, such that Spanish-speaking children who hear a story about a girl who *es* shy are more likely to think the girl will be shy at other parties and 2 years in the future, as compared to those who heard that the girl *está* shy. A second example, the Twenty Statements Test, a common measure of self-construal, consists purely of 20 statements that begin "I am . . ." and ask the participant to complete the sentence. The usual findings are that Eastern respondents are more collectivistic, in that they more often give social role or category responses (e.g., "I am a man") compared to American respondents, who give more personality-oriented responses (e.g., "I am loud"). However, even the seemingly benign "I am" construction can be problematic, because the direct translation into Chinese is *Wo shi*—a construction "usually followed by a noun phrase and only occasionally an adjective" (Hong, Ip, Chiu, Morris, & Mennon, 2001). When Hong et al. dropped the *am* (or the *shi* in Chinese) from the Twenty Statements Test, Hong Kong and American participants gave very similar responses.

An issue of translation also seems to have partially led to the debate between Au (1983, 1984) and Bloom (1981, 1984) over the issue of Chinese speakers' inclination to engage in counterfactual thinking. Depending on how the stimulus materials are written and the subject population one uses, the number of counterfactual thoughts generated by Chinese (and English) speakers varied dramatically. Au argued that Bloom's materials were translated into "nonidiomatic" Chinese, and she argued that she could increase counterfactual reasoning when the materials were translated into a more idiomatic form. Ironically, Au claimed, Bloom's English-to-Chinese translators had rendered his materials less intelligible by translating the literal meaning instead of using forms more idiomatic to Chinese. Bloom (1984, p. 283) defended his translations (done by "native Chinese-speaking professors at the National Taiwan University") and in turn criticized Au's story materials. Translation, even when done by experts, is no simple matter.

TRANSLATIONS, QUANTIFIERS, AND REFERENCE GROUP EFFECTS

Even within the English language, there can be a translation issue from region to region. Spanking, for example, means something different to Northerners and Southerners in the United States, because in the South, spanking is much more likely to be done with a paddle or a switch. Even with this difference in meaning, Southerners are more likely to favor a “good hard spanking.” However, in analogous cases, one can imagine that differences in meaning could lead one to quite misleading conclusions. For example, if the word *argument* is taken to mean any sort of disagreement that involves raised eyebrows in culture A, whereas it means a shouting match that would drown out a rock concert in culture B, one might find that the frequency of “arguments” in culture A is startlingly high compared to that in culture B. In this case, the ambiguity in the word *argument* adds not only noise but also bias.

These differing definitions and standards can arise partly out of reference group effects that Heine and colleagues (2002) have explored. So, for example, when a respondent is asked whether she is “creative,” she first needs to figure out what “creative” means (“Does it mean that I paint and write poetry? Or does it mean that I fire off snappy one-liners in the break room?”). Additionally, she needs to figure out what groups she should be comparing herself against (“Am I creative compared to chimpanzees? Compared to people my age? Compared to my fellow bank tellers? Compared to other Americans? Compared to other Americans *and* to the people in that other unknown culture that the researcher will be studying? Compared to all the humans in the world? Compared to some absolute standard that I have personally developed?”). People may not explicitly ask themselves these questions, but some definitions have to be implicitly constructed, and some comparison standard has to be set.¹⁰ This is done with the aid of a reference group, implying, as Heine and colleagues (2002) have shown, that when a Japanese person answers a question such as “I have respect for the authority figures with whom I interact,” he or she may be thinking of a very different comparison standard than that of an American (Singelis, 1994). In Heine et al.’s (2002) study, European Canadians’ scores on an interdependence scale were equal to Japanese scores when no comparison group was given, were higher than Jap-

anese scores when members of each group were specifically told to compare themselves to people in their own culture, and were lower than Japanese scores when members of each group were specifically told to compare themselves to people in the other culture. (Obviously, people have to be knowledgeable about their own culture and other cultures to make these comparisons meaningful. But more generally, the point is that responses to Likert-scale attitude questions depend greatly on the reference group the respondent is using).

We can try to figure out the standards of comparison by asking respondents probing questions, or we may give respondents questions that ask specifically about the types of behaviors we are interested in. Furthermore, we can follow Schwartz’s (1999) advice to avoid “vague quantifiers” such as *frequently*, *sometimes*, and so on, and instead ask for objective numbers. Thus, it is possible to turn some questions, such as “I frequently engage in violent pastimes” into “I go hunting ___ times per year,” but it will not always be either possible to do so or meaningful to do so.

Translating Situations and Behaviors

By avoiding vague quantifiers and by asking more objective, behavioral questions, one generally lessens both the error and bias that results when participants from different cultures construe the question differently. High-impact lab experiments that call for specific behaviors go even further toward doing so. However, one still must be sure that the situations one constructs for a study and the behaviors observed translate from one culture to the next. The bargain one strikes for the sake of clarity is this: The more one specifies very particular situations, and the more narrowly one operationalizes a variable, the more one is implicitly pushed toward examining a phenomenon as an etic (universal) construct that is played out the same way across cultures—rather than as an emic or more culturally specific construct that is approached in a culture’s own terms. Thus, the trade-off is that the more one is concrete, the less one will have error and bias about that particular set of behaviors; but also the more one is concrete, the greater the risk of missing emic phenomena or constructing what Triandis (1994, p. 69) called pseudoetics (false etics; see also LeVine, Chapter 2, and Triandis, Chapter 3, this volume).

This is essentially Cronbach's (1990) point about the fidelity-bandwidth trade-off, as applied to culture. Generally, there is a trade-off such that variables narrowly defined (low in bandwidth) can be measured with high fidelity (less noise), whereas those that are broadly defined across a range of observations (high in bandwidth) have lower fidelity (more noise). (*Note:* High bandwidth is *not* the same as simply being vague). Thus, one may measure, say, intelligence (Sternberg, Chapter 22, this volume), secure and insecure attachment (Morelli & Rothbaum, Chapter 20, this volume), reasoning ability (Norenzayan et al., Chapter 23, this volume), self-esteem (Kitayama et al., 1997), competitiveness, feelings of interdependence and connectedness (Brewer & Yuki, Chapter 12, this volume), religious behaviors, emotional expressions, passive-aggressive behaviors, mental health and illness (Marsella & Yamada, Chapter 33, this volume), patriotism, extroversion, love (Hatfield, Rapson, & Martel, Chapter 31, this volume), and so on. And the more concretely and precisely one measures these constructs, the less "noise" there will be. However, precision may also mean narrowness, and the narrower the construct is operationalized, the more likely it is to privilege one culture's definition of the construct over another's.

The coding of secure versus insecure behavior in the Strange Situation task is a possible illustration of the problem of narrow definitions (see Morelli & Rothbaum, Chapter 20, this volume). However, there are cases in which the problem is not simply the coding of behavior in a situation; rather, the problem is that *the entire situation* itself fails to translate. Shweder (1997, p. 155) provides a humorous example:

A team of psychologists from Scandinavia was doing comparative research [on] variations in the "universal" family meal. They wired ahead to a prominent local psychologist in this rural area of India and asked him to arrange for a family meal. . . . Being civil and polite, he did so, without ever telling them that in rural India there is no such thing as a family meal. The Scandinavian research team spent a few days in the area. The local psychologist convinced some family to sit down at a table together and food was served and they were filmed. But everyone was uncomfortable. Avoidance relationships were being violated. People kept getting up from the table and leaving. No one ever explained to the visitors that family meals should not be presumed to be part of some

universal grid. They returned home, coded the materials, and made some sort of inference about what was going on, without really ever understanding what was really going on.

Situations and behaviors—in both experimental paradigms and observational studies—can fail to "translate" across cultures. Ultimately, there is no substitute for background reading, having informants or collaborators familiar with the culture, pretesting measures, probing respondents for their understanding of concepts and behaviors, and using a combination of investigative techniques—some of which are "operant" methods, in that they are loosely controlled, exploratory, and driven primarily by the respondent, and others of which are "respondent" methods in that they are more tightly controlled, well-defined, and driven by specific hypotheses of the experimenter or interviewer (Triandis, 1994, p. 80).¹¹

Subquestion 2: "What Are the Cost-Benefit Trade-Offs of Surveys versus Experiments?"

Strategies for Questionnaires and Experiments

Often, a research question can be plausibly answered by operationalizing the hypothesis in a naturalistic observational study, a questionnaire (open- or closed-ended), or a high-impact lab experiment. Again, the best answer about which one should do is: all of them. However, pragmatic concerns often dictate that one rather than the other needs to be done, or that one rather than the other at least needs to be done first. In nonqualitative cultural psychology research, this often comes down to the question of whether one should begin with questionnaires or experiments. There are two schools of thought on this issue. According to one school of thought, investigations need to start by casting the widest possible net to explore a phenomenon. The questionnaire (again either open- or closed-ended) is far more efficient for this purpose. Not only is it possible to run many, many participants at once, but it is also possible to ask about a wide array of situations and an extended history of behaviors. Say, for example, one is studying cultural differences in coping with stress across cultures. In a matter of a few pages, it is possible to ask about relationship stressors, academic stressors, work stressors, economic stressors, and so on. It is possible to ask about a history of situa-

tions that have happened in the past and to ask respondents to speculate on situations that might happen in the future. One can in this way get answers that cover a huge variety of situations.

The question, however, is whether and to what degree one should trust those answers. A mundane concern is that response set biases can potentially plague any sort of questionnaire research; however, what is particularly troublesome to cross-cultural researchers is the possibility that cultures are differentially susceptible to different response sets. For example, people from hierarchical cultures may be more likely to give extreme responses that use the end points of the scales; those from collectivistic cultures may be more likely to show the acquiescence bias (Johnson, Kulesa, Cho, & Shavitt, 2005; Lalwani, Shavitt, & Johnson, 2006; Triandis, 1994). Some protections can be put in place (e.g., having an equal number of reverse-scored and nonreverse-scored items can lessen problems created by the acquiescence bias), and one can do as much as possible to lessen the problem of social desirability biases (e.g., disguising the dependent variable, allowing participants to believe that their responses are anonymous, and truthfully assuring anonymity and confidentiality can reduce impression management effects).

However, there are deeper problems with any questionnaire data that can be very difficult to overcome. These involve problems in which the participant may not be able to correctly tell us about his or her behavior or attitudes, *even if he or she wants to*. Depending on the domain, people can have great difficulty identifying the reasons for their actions, articulating their preferences, predicting their future behavior, and predicting how they will feel about their future outcomes (Nisbett & Wilson, 1977; Gilbert & Wilson, 2000; Wilson & Dunn, 2004)—even when extremely important life events are involved (Pauker & Pauker, 1979). Of course, these points should not be pushed to the extreme (I can tell you that I prefer watching a movie to being hit with a hammer; I can tell you why I have that preference; and I can safely predict how I will feel after either experience). However, the difficulty in getting accurate self-reports is one reason some researchers prefer experiments and find that they produce bigger differences than do questionnaires.

The second school of thought on where to begin is to follow Kurt Lewin's advice and "start strong." In this case, one might look to a high-impact lab experiment to highlight a large effect. The following is very far from a perfect comparison, but consider a few examples. In national surveys, when asked whether they would approve of a man punching another man who "was drunk and bumped into the man and his wife on the street," around 7% of non-Southerners said "yes," whereas around 16% of Southerners did so (the effect size is small, r is approximately .15). In an experiment, when Northern and Southern university students were bumped into by a confederate and called an "asshole," 35% of Northerners responded with at least as much anger as amusement, whereas 85% of Southerners did so (the effect size is large, r is approximately .5; Cohen & Nisbett, 1994; Cohen, Nisbett, Bowdle, & Schwarz, 1996). On a questionnaire, when Northern and Southern students are asked how they would react to an annoying confederate who kept hitting them with paperwads, their predicted responses did not differ. However, when the experiment is actually run, differences do occur, with effect sizes in the medium and large range, depending on the specific behavioral measure (Cohen, Vandello, Puente, & Rantilla, 1999).

Effects from experiments have the potential to produce much bigger differences than questionnaires do, precisely because they are highly involving. Such highly involving studies are more likely to involve "online processing" compared to studies that do not psychologically engage a participant (Kitayama, 2002). This is likely to be particularly important for situations and behaviors that involve a lot of emotion. Emotions transform the way we experience the world, and in a "cool" state, it is not so easy to predict how one would behave in a "hot" state (Loewenstein & Schkade, 1999). Milgram (1974) provided a classic example. There is little chance that the behavior of subjects in Milgram's high-stakes, high-pressure experiment would have been predicted by anyone in a cold state filling out a questionnaire. In terms of more prosaic examples, anyone who has ever broken their diet after seeing a particularly delicious desert, said something in anger that they did not mean, or even bought too much at the grocery store because they were hungry, can attest to the simple truth that hot-state behavior is very different from,

and cannot easily be predicted by, statements and behaviors made in a cold, detached state.

Even attitude questions that describe what might be a compelling scenario can only be so involving and even these often leave the situation underspecified. One can create the situation to be just right in the laboratory, but describing it on paper quickly becomes unwieldy. The bump and “asshole” experiment is an example:

“Imagine that you are in an unfamiliar building and you are walking along, minding your own business. You aren’t in a hurry and no one is with you. Then someone who is about your size and who is wearing his baseball cap backwards starts to swagger down the hall, looking slightly miffed because you had earlier—through no fault of your own—interrupted his filing job. It’s a tight hallway that you can both fit through if you each give a little, but as he walks down the hall, the man bumps into you firmly with his shoulder and calls you an “asshole” in a tone of voice that makes you think he isn’t joking and he believes what he is saying. He definitely knows that he hit you, and though it’s not clear if the bump was intentional, the “asshole” sure was. You know you weren’t really at fault, and you may suspect that he knows this, too. Then he just keeps on walking without apologizing. He is neither stopping to directly confront you, nor is he running away. Rather, he intends to just walk on, like you’re not going to do anything about it” [and so on].

In a live experiment, one can set up all the particulars to trigger the response in a way that is hard to do with underspecified questionnaire items.

Note here that the trade-offs between surveys and experiments perfectly complement each other. Surveys can ask about a wide array of situations but in a great many cases provide underwhelming evidence about differences in any particular situation. On the other hand, experiments can produce big differences in situations that we have constructed to be “just right.” However, we cannot know whether the results from our “just right” situation generalize; and for that, questionnaires that allow us to ask about a variety of situations (without having to create them in the lab) can help a great deal.

Subquestion 3: “What Other Methods Can Provide Convergent Evidence?”

Beyond the Questionnaire and Lab Experiment

Cultural psychology is pluralistic in its methods, and it takes seriously the notion that converging evidence from diverse methodologies is the best type of support for an argument (Ellsworth & Gonzalez, 2003). A set of three attitude surveys will have weaknesses common to all attitude surveys; three lab experiments will have weaknesses common to all lab experiments; in general, three studies, all of the same methodology, are not as strong a support for a hypothesis as are three studies conducted with diverse methods. The weakness of any one methodology should be offset by the strengths of another.

As mentioned previously, cultural psychologists not only inherit all the weaknesses inherent in their home discipline but they also encounter new methodological problems that arise when they study a phenomenon across cultures. Hence, the standard appeal to all researchers to obtain converging evidence across methods is an even stronger imperative for cultural psychologists, who face extra methodological burdens. Thus, it is important to note that we are not and should not be restricting ourselves to operationalizing hypotheses using either paper-and-pencil questionnaires or experimental paradigms in traditional settings. Two additional techniques highlighted below are field “experiments” and the analyses of cultural products.

FIELD EXPERIMENTS

“Field experiments” is often used as a catch-all term for studies conducted outside the laboratory. Some of these are actually experiments in that they involve a manipulated variable (in addition to the nonmanipulated variable of culture). Others are more properly called “field studies,” because there is no manipulated variable. These latter studies may involve experience sampling methods (in which participants are beeped at various intervals to complete questionnaires about their experiences as they go through the day; Diener & Tov, Chapter 28, this volume; Mesquita & Karasawa, 2002; Mesquita & Leu, Chapter 30, this volume) or they may involve (1) naturalistic observations in which the researcher has no role except to observe as discreetly as possible or (2) real-

world reactions to events or stimuli that were actually created by the researcher (usually surreptitiously). An example of a naturalistic observation would be Levine and Norenzayan's (1999) study on the pace of life in different cultures, in which they measured the average walking speed in the business districts of various cities and also tracked the accuracy of public clocks. An example of a field study in which the researcher does surreptitiously provide a stimulus would be Levine, Martinez, Brase, and Sorensen's (1994) helping study, in which they had confederates in various downtown business districts pretend to be blind people needing help crossing the street, or had them walk along and drop their pens to see if passersby would pick them up, and so on. Such naturalistic and field observations have the advantage of capturing behavior outside the laboratory, where one can avoid artifacts that might result from impression management concerns, participant reactivity, stereotype threat, "good subject" effects, and so on. In addition, because they occur outside the confines of a university, such studies are likely to include samples broader than college student populations.

How much these studies mimic "typical" behavior in the real world often depends on how unusual a researcher's intervention is. For example, Feldman (1968) had researchers act as either natives or foreigners and (1) approach people in Boston, Paris, and Athens to ask them to mail a letter (relatively unusual); (2) take taxi rides to see whether the driver would cheat the passengers (normal); (3) ask for directions (normal), and so on. It is worth noting that the unusual task also had the most unusual results, being the only task in which Bostonians showed the greatest ingroup bias, preferentially mailing letters for fellow Americans rather than foreigners.

The field study can be conducted both with individuals as (unknowing) participants and also with organizations as unknowing participants. Salancik (1979) urged organizational researchers to conduct such experiments when he advocated "tickling" the organization to see how it responds and what this might reveal about the organization's true behavior as opposed to its stated mission. Putnam (1993) employed one such field study when he examined the effectiveness of various regional governments in Italy. A citizen (actually a confederate of the researcher) wrote to bureaucracies in each region with three requests. If no replies were received, follow-ups were made with phone calls and personal visits.

This "street-level" measure of responsiveness actually correlated reasonably well with other, very different measures of the regional governments' effectiveness; that is, bureaucratic performance in these field studies correlated significantly with the regional government's ability to pass budgets on time, enact reform legislation, and keep a stable cabinet. Because cultural psychologists can and should consider institutions, as well as individuals, as carriers and products of a culture, the field experiment that tickles an organization to investigate its goals (Salancik 1979), examines its responsiveness (Putnam, 1993), or finds out what is embraced versus what is stigmatized within that organization (Cohen & Nisbett, 1997) can be an important complement to traditional research paradigms that examine the individual as the unit of analysis.

Finally, there is an excellent opportunity to conduct field experiments as part of an intervention study. There are few researchers today who would re-create Sherif's (Sherif, Harvey, White, Wood, & Sherif, 1954) classic Robbers Cave experiments, setting up summer camps and introducing various manipulations. However, intervention programs—through public health campaigns, social work agencies, schools, political campaigns, and environmental programs—happen often in the world around us. These programs sometimes target a particular cultural group and other times focus on a general population, which may also have many cultural subgroups. The opportunity for cultural psychologists to propose some of these interventions, contribute to their design, or simply observe the results gives researchers a chance to study how different types of programs affect people from different cultures, how different chains of communication and influence get activated in different groups, how different cultural traditions either assimilate or accommodate new information and patterns of behavior, and so on. Such opportunities for field experiments (which use random assignment) or observational studies (which may have matched, if not randomly assigned, controls) give cultural psychologists an excellent chance to move into "the real world."

CULTURAL PRODUCTS

Cultural products exist out in the world. They are the laws that are passed, the advertising techniques that are used, the architectural

styles that are followed, the television programs that are made, the newspaper articles that are written, the goods that are consumed, the names that are given to people and places, the words that are used, the dictionaries that are compiled, the art that is produced, and so on. All of these are within the purview of cultural psychologists. In fact, all of these have been used by researchers investigating culture. Morris and Peng (1994), and Lee, Hallahan, and Herzog (1996) have analyzed Chinese and American newspaper articles to examine the causal explanations offered for various events. To examine Asian versus U.S. differences in holistic versus analytic perception, Nisbett and Masuda (2003) examined East Asian and American artwork to show that background rather than central figures were more emphasized in East Asian art; meanwhile, Miyamoto, Nisbett, and Masuda (2006) photographed and analyzed street scenes in Japanese and American cities of various sizes to look at the extent to which objects and buildings filled the streetscapes and blended together or were spaced apart so as to stand out and emphasize their status as discrete entities. To examine the extent to which regional cultures legitimated violence, Baron and Straus (1989) examined viewership of violent television shows, subscription rates for violent magazines, per capita production of college football players, and state laws related to corporal and capital punishment. Similarly, Kelly (1999) examined place and business names across the United States and found that Southern states had more violent names (e.g., Gun Point, FL; War, WV; Battle Ax Church in Texas; or Gunsmoke Kennels in Alabama). To examine persuasion in independent and interdependent cultures, Han and Shavitt (1994) and Kim and Markus (1999) examined Korean and American advertisements for their appeals (e.g., “The art of being unique” vs. “Sharing is beautiful”). To look at the diminishing vocabulary of shame in American culture, D. Cohen (2003) looked at the prominence given to “shame” compared to the prominence given to words such as *guilt*, *embarrassment*, or *humiliation* in the dictionaries and thesauruses throughout various decades of the 19th and 20th centuries. Even the many translations of the Bible reflected how shame (relative to guilt) has been falling out of religious vocabulary. The King James Bible (1611) had a shame:guilt ratio of 5:1; at the turn of the 20th century Bibles had a ratio of

3:1; and modern translations have now reduced the ratio to 1:1.

Some of these examples are aggregate behaviors; that is, they represent individual, “independent” decisions by people that are merely summed together. Readership of violent magazines, for example, is an aggregate. Other such products are more collective; that is, they require some form of collaboration to produce. The streetscapes of Miyamoto et al. (2006) for example, reflect the decisions of zoning boards; architectural consultants; builders and business owners who want to make their spaces appealing to customers, renters, landlords, and so on. Such collective products are not the product of any one person or group, but instead come out of the push and pull of various forces within the culture. (As is discussed in the “Interpretation” section, aggregates and collective representations may differ in ways that can be quite informative about the culture.)

Of course, the benefit that one gains examining a *collective* representation can also be a drawback sometimes. With collective products, for example, it can be difficult to determine whether the product is created mostly as a function of top-down choices made by the elites of a culture or instead reflects a more bottom-up process driven by preferences of the mass public. One cannot pinpoint one particular causal agent, though one can potentially examine the processes by which such cultural products are produced.

MORE QUALITATIVE METHODS

Research methods that are more qualitative are not the subject of this chapter. However, such methods can be a very valuable complement to the more quantitative methods described here. More qualitative studies can add richness, depth, and vividness that more quantitative studies cannot (LeVine, Chapter 2, this volume; Miller, Fung, & Koven, Chapter 24, this volume). They add the *qualia* necessary for understanding what it is like to be an encultured human being (Shweder, 1997, Chapter 34, this volume, and, in a different context, Nagel, 1974).

It should be noted that the distinction is really between studies that are “more qualitative” or “more quantitative.” In qualitative methods, there is usually some degree of quantitiveness, because there is usually some form of implicit counting. The statements that

“a few,” “a minority of,” “a majority of,” “many,” or “most” informants did a certain thing or felt a certain way reflects some sort of tally the researcher was making. Similarly, our quantitative methods require some sort of qualitative judgment whenever we, for example, analyze something a participant has written or said, in terms of the tone, degree of complexity, or affective content that it shows. (For that matter, on many self-report scales, we are asking participants to quantify their own judgment that they are, for example, feeling “mildly anxious” about something, “very satisfied with their life,” “extremely in love” with their spouse, or “somewhat disgusted.”)

In still other cases, we may quantitatively analyze data gleaned from the Standard Cross-Cultural Sample or Human Relations Area Files. Much of the research in these files was derived by anthropologists using qualitative methods or judgments. In this case, we are then using a quantitative method to aggregate qualitative data.

Summary

In summary, in addition to all the standard operationalization issues one must worry about, the cultural psychologist must construct variables that are interpretable and convincingly operationalize a construct when seen through (at least) two different cultural lenses. Thus, the cultural psychologist faces the additional problem of “translation,” broadly defined to include language, behaviors, situations, reference groups, and so on. Cultural psychologists do have one advantage over their more discipline-bound colleagues, however. The field’s youth and generally pluralistic outlook should foster a pluralism in methods as well. All methods have their individual weaknesses. However, with the field’s pluralistic acceptance of diverse methodologies, cultural psychologists are given a full toolkit of techniques that can be used for both initial exploratory work and for producing the sort of convergent evidence across methodologies that makes for convincing social science arguments.

INTERPRETATION

Careful consideration of causal issues, sampling, and operationalization should lessen (but not eliminate) the difficulties of interpreta-

tion after the data are collected. There are certain inevitable problems that we encounter, and some of these were discussed earlier. However, there are other interpretational issues that arise, independent of the artifacts from any one study. Two issues considered below involve (1) how we interpret similarities and differences between cultures, and (2) how we interpret data that do not converge.

Subquestion 1: “Am I Really Understanding What Is Similar and What Is Different in the Cultures?”

“Quantifying” Similarities and Differences

The issue of similarities and differences between cultures occurs on multiple levels. At one level, the issue of heterogeneity within cultures can make differences between cultures look small in comparison. Various effect size measures can be employed to look at how “big” a cultural difference is; one of these, Cohen’s d is the ratio of the difference in the means to the standard deviation (SD) within (pooled). This d can also be translated into an “intuitively compelling and meaningful” u_1 , the percent of “the area covered by both populations combined that is not overlapped” (Cohen, 1988, p. 21). At a “small” d of .2, u_1 is 15%; at a “medium” d of .5 (which Cohen says may be “conceived of as one large enough to be visible to the naked eye”—that is, noticeable “in the course of normal experience”), u_1 is 33%; at a “large” d of .8, u_1 is 47% (pp. 22, 26).

Under this interpretation, d and u_1 may be considered as possible quantitative indices of similarities and differences between cultures. However, d (and u_1) are indicators of the size of the differences, *not* their importance. First, big differences can be trivial (as an absurd example, there is probably a culture effect such that Italians like eating pizza more than Saudi Arabians do, and the effect size is probably large here). Conversely, small and moderate effects may be quite important for any number of reasons: (1) Small differences at the center of the distribution can lead to large differences in the tails of the distributions (e.g., men may be somewhat more aggressive than women, on average, but men are tremendously more likely than women to be mass murderers); (2) small differences may have huge practical consequences. (For example, a shift of 5 percentage points would change who won the popular vote in many presidential elections, yet 5 per-

centage points translates to only one-tenth of a standard deviation for an evenly divided electorate. A 60-40 political “landslide” that might signal a major political realignment would translate to a difference of only four-tenths of a standard deviation; Ross & Nisbett, 1991); (3) small differences may become large differences when they accumulate over time. This is important when differences grow exponentially, as in compounding investments, in which total return is a function of initial investment multiplied by $(1 + r)^n$, where r is the rate of return and n is the number of compounding periods. And it is also true when accumulation involves only increasing the magnitude of the raw numbers involved, as in, for example, baseball. Following Abelson (1985), the correlation between a baseball player’s batting average and success on any given trip to the plate is .05, equivalent to a d of .1. What separates Hall-of-Famers from benchwarmers is that differences accumulate over the course of a season or career; and (4) small and moderate differences may have important theoretical implications. (For example, the average effect size of the mere exposure effect is somewhere around a d of .4; the average effect for rewards undermining intrinsic motivation is around a d of .35; the average effect sizes for the relation between personality and various measures of heart functioning are in the $d = .2-.4$ range; Bornstein, 1989; Deci, Koestner, & Ryan, 1999; Lyness, 1993; Miller, Smith, Turner, Guijarro, & Hallet, 1996.) Similarities and differences between cultures may thus be quantified, but they cannot be interpreted without thinking about either practical or theoretical importance.

Controls and Boundaries

A second issue that arises in thinking about similarities and differences has to do with the importance of both boundary conditions and comparison conditions. Because of various response bias effects, a culture main effect may be difficult to interpret by itself. For example, in cases when one is measuring performance on some test, it is good to have definable parts of the test where one expects a cultural difference, and definable parts of the test where one either does not expect such a difference or expects a reversal. Thus, for example, if one expects culture A to show better memory than culture B for social stimuli, it is helpful to show that there are no differences (or a reversal) for

nonsocial stimuli. If culture A does better than culture B for social stimuli but there is no comparison condition of nonsocial stimuli, one cannot rule out the possibility that culture A simply took the task more seriously.

In this case, a comparison condition or comparison variable attempts to rule out the possibility of response biases that may create artifacts. In other cases, a comparison condition is theoretically meaningful because it puts boundary conditions on the phenomenon one is studying. Thus, for example, if a researcher wants to talk about culture A as a culture of honor, in which people are primed to be aggressive after being insulted, it is also helpful to have a control condition in which there is no affront and, hence, no greater readiness for aggression in culture A. The control condition aids in circumscribing the phenomena to honor-related infractions and helps rule out the explanation that culture A is simply a chronically aggressive culture across the board. Finally, some researchers may also choose to run control conditions that are expected to produce similarities that serve as an “anchor” in the way we think about the two cultures, preventing readers from drifting off into an extreme relativism.

Unfortunately, going for a culture \times condition interaction (rather than simply a culture main effect) entails a large loss in power when one does not expect a crossover interaction. Think, for example, of a 2 (culture) \times 2 (control vs. experimental condition) design in which one predicts a difference in the experimental condition and no difference in the control condition. Suppose that, as expected, there is a simple effect difference between the two cultural groups in the experimental condition ($t_1 = 2, p < .05$). Suppose further that, as expected, there is no simple effect difference between groups in the control condition ($t_2 = 0, p > .99$). Assuming that the same pooled error term is used across all of the t -tests, the t for the interaction term will be $(t_1 - t_2)$ divided by the square root of 2. (In this case, where $t_1 = 2$ and $t_2 = 0$, the interaction $t = (2 - 0)/(\text{square root of } 2) = 1.4, p > .15$) (Abelson, 1995). The control condition has already required the experimenter to double the n ; but in addition, to make up for the loss in power, the experimenter will have to run many more participants than this to have a decent chance of detecting the interaction. (Of course, using Abelson’s rule, if the control condition goes the *opposite* way to

that of the experimental condition and the control condition difference is at least 42% as big as the experimental difference, there is a gain of power.) Designing studies in terms of interaction effects requires more thinking beforehand about appropriate comparison or boundary conditions, and it often requires more time and money to run more participants. However, the clarity such conditions can provide in interpretation can be well worth it.

The Necker Cube of Culture

A third issue about similarities and differences is more abstract, but it goes to the heart of what the cultural psychology field is or will become. That is, to the extent that cultural psychology can discuss both similarities and differences across cultures, it will be a richer field than if it can discuss only differences (see also Norenzayan & Heine, 2005; Konner, Chapter 4, this volume).

Cultural differences are embedded within similarities, and cultural similarities are embedded within differences. Depending on how we look at it, the similarities can look greater or the differences can look greater. A rich cultural psychology will force us to look at the “Necker Cube” of culture. Like the surfaces of the Necker cube, what pops out at us in our understanding of cultures will shift back and forth in terms of the ways the cultures are similar at one level and different at another. The implication is that cultural psychologists may design their research programs to be strong on both *integration* and *differentiation*. Phenomena that are different on the surface may have a similarity in terms of their deeper structure, and cultures that are similar on the surface may be quite different in their deeper structure. Two examples—one derived directly from empirical work, the other loosely derived from it—help to illustrate the point.

Starting in the 1990s, Heine and Lehman (1995, 1997a, 1997b, 1999; Heine, Takata, & Lehman, 2000; Heine, Kitayama, & Lehman, 2001; Heine, 2005, Chapter 29, this volume) began to publish an astonishing line of research, showing that some very robust self-enhancing biases did not seem to operate in Japan. One of their findings involved the “spread of alternatives” paradigm from cognitive dissonance research, in which participants make a choice and are then shown to rationalize that choice as a way to protect their self-esteem.

Heine and Lehman showed that this classic effect does not hold for the Japanese, presumably because dissonance effects, like other self-enhancing biases, did not operate in this population (Heine, Lehman, Markus, & Kitayama, 1999).

Two lines of research qualified Heine and Lehman’s finding in important ways, however. In one, Hoshino-Browne et al. (2005) replicated the Heine and Lehman (1997a) result, showing that Asian Canadian participants (unlike their European Canadian counterparts) showed no rationalization effect when they made a choice for themselves. However, they also ran another condition in which participants were asked about a close friend’s preferences, then had to choose a gift for this friend. In this condition, the findings reversed: The European Canadians showed no dissonance effect, whereas the Asian Canadians now began to rationalize their choice. Thus, it was not that dissonance phenomena existed in one culture but not another. Rather, both Asian Canadians and European Canadians rationalized to protect the self; however, the selves they were protecting were very different. The European Canadians were protecting the competent, rational, independent self that knows what it wants and goes out and gets it. The Asian Canadians were protecting the relational, interdependent self that is sensitive to other people and attends to their preferences. To make their point stronger, Hoshino-Browne et al. (2005) showed that a traditional self-affirmation task (which bolsters the self and typically wipes out the need to rationalize for European Americans) had no effect on Asian Canadians. Instead, they showed that only a new self-affirmation task that bolstered the interdependent self and shared values could wipe out dissonance effects for Asian Canadians.

In a separate but related line of work, Kitayama, Snibbe, Markus, and Suzuki (2004; Kitayama, Duffy, & Uchida, Chapter 6, this volume) explored the idea that choices may threaten a person’s self in very different ways in Japanese and American culture: A bad choice may threaten an American independent self, because it means that the self is not competent or efficacious. A bad choice may threaten a Japanese interdependent self, because others may then think of the person as foolish. Japanese may be relatively free of the independent threat when they make a choice but feel fully the interdependent threat when they make a

decision. In several studies, Kitayama and colleagues (2004) replicated the Heine and Lehman (1997a) effect, showing no dissonance effects for Japanese. However, when Japanese participants were first forced to think about self-relevant others (e.g., by asking participants about what the average student's preferences would be), dissonance effects appeared in full force. Even putting participants in front of a poster that showed schematic line drawings of faces was enough to prime such interdependence concerns and produce dissonance effects for the Japanese. Like Hoshino-Browne et al. (2005), Kitayama et al. (2004) showed that dissonance occurred in the two cultures, but it was a very different kind of dissonance, invoking different threats to a different kind of self. Neither the Hoshino-Browne et al. (2005) nor the Kitayama et al. (2004) papers are a rejection of Heine and Lehman's (1997a) finding. They extended the finding by integrating (showing similar processes of rationalization following self-threat) and differentiating (showing how such threats and rationalizations were quite different for the two groups) to give a richer picture of self-threat, rationalization, and choice in the two cultures.

A different line of research pursued by Shweder, Rozin, Haidt, Miller and colleagues is not as tightly bound to particular studies, but provides another example of work that integrates and differentiates (Rozin, Lowery, Imada, & Haidt, 1999; Shweder, Much, Mahapatra, & Park, 1997). Shweder and colleagues developed a rich account of the "Big Three" of morality, showing how various ethical breaches cluster into events that violate principles of autonomy, community, or divinity (see also Haidt, Koller, & Dias, 1993; Miller, Chapter 19, this volume; Morelli & Rothbaum, Chapter 20, this volume; Rozin, Chapter 16, this volume). These three "ethical discourses" are found in the United States and India. However, the countries differ in which ones get foregrounded and which get backgrounded: In the United States, concerns with autonomy are foregrounded, whereas in India community and divinity are foregrounded.

Shweder and colleagues (1993) suggest *karma* as an "overarching moral metaphor" for South Asian morality, where *karma* is seen as a theory of personal responsibility. They then describe how the overarching concept of *karma* and the three subcategories of community, autonomy, and divinity also connect to American notions of personal responsibility,

communitarian concerns (e.g., secondhand smoke), the "moralization" of unhealthy behaviors as bad or disgusting, and an emergent American "neo-Puritanism" (Rozin, 1999; Shweder, 1993). The collective body of work is complex in the way it illuminates both the underlying similarities and differences in U.S. and Indian explanations of morality and suffering. As in the work by Hoshino et al. (2005) and Kitayama et al. (2004), the cultural analysis is like a Necker cube: Whether it is the differences or the similarities that strike us depends on the angle from which we are looking at the phenomena.

Subquestion 2: "What Happens If My Data Do Not Converge?"

The answer to methodological problems lies in thinking through our theories and collecting convergent evidence from multiple empirical methods. This answer is fine. However, what happens when the data do not converge? That is, what happens when the data from one methodology point to a different conclusion than the data from another methodology? We need to investigate whether this divergence is a result of artifacts or whether it is telling us something quite meaningful, and if so, what?

Artifacts

The first step involves thinking about and investigating possible methodological artifacts in our data and possible differences introduced by the use of different sampling techniques in different studies. In addition to any of the issues raised previously, culture researchers may have to watch out for other methodological artifacts because of the types of data with which we sometimes work. For example, statistical artifacts arise from working with aggregate data and grouped data. A standard example of *Simpson's paradox* is that shoe size is correlated with income. There may be no relationship between shoe size and income when considering just the men, and no relationship when considering just the women. However, when they are put together, there is a relationship between shoe size and income, because men, on average, have higher incomes and bigger feet. Consider a potential cultural example: There may be a negative relationship between an extended family support system and personal happiness. Within individualist cultures, more

family support may mean more happiness; within collectivist cultures, the same may be true. However, when the cultures are put together, the relationship between support systems and happiness reverses, because collectivist cultures tend to have more family support and are on average less happy than individualist cultures.

When working with aggregate data, a researcher needs to be cautious of the *ecological fallacy*, in which one generalizes from aggregate-level data to individual processes. As a simple example, suppose that U.S. states with high numbers of educated people also had high rates of violent crime. The “generalization” from the aggregate level to the individual level would be that more education makes people more violent. The opposite is true, though: More education makes people less violent. It is just that states with higher numbers of educated people tend to have more urban areas, and more urban areas tend to have more violence.

Yet another problem arises when we try to extrapolate from within-group differences to between-group differences. This was famously on display in discussions of Herrnstein and Murray’s (1994) *The Bell Curve*. In very rough form, the reasoning was as follows: We know that intelligence is highly heritable (i.e., genetic), and we know that there are differences on IQ tests between European Americans and African Americans. Therefore, the difference in IQ scores between European Americans and African Americans must be genetic. To illustrate the potential problems in going from a within-group explanation to a between-group explanation, Feldman (cited in Cavalli-Sforza and Cavalli-Sforza, 1995, p. 274) proposes this parallel example. Take two groups of 50 white Americans. We know that skin color is highly heritable, and this will be true within each of the two groups. Now send one group to a sunny place (Miami) and the other to a cloudy place (Champaign–Urbana) for the next year. Within each group, genetics will still predict skin tone, but the difference between groups is now the result of climate, not genetics. A cultural example follows: Suppose that more education predicts greater support for gender equality in both the United States and Denmark. One cannot then infer that Danes are more egalitarian because they tend to be better educated than Americans. In fact, Danes are not better educated; the powerful within-group

variable of education has no role in explaining the between-group difference.

These problems, which all stem from the “correlation is not causation” problem, are easy enough to spot when they are as obvious as the examples just given. However, many problems in research are much more subtle, and investigators need to be wary of these statistical artifacts in designing their studies and interpreting their data.

Does the Nonconvergence Represent a Real Cultural Phenomena?

Suppose, however, that no obvious methodological issues or statistical artifacts explain nonconvergent data. Obviously, we need to collect more data, but in what direction do we go? To decide this, we have two choices. We can believe either our data or our theory. (Here we run into an actor–observer problem. Einstein’s dictum was that, as researchers, we tend to believe our theories more than our data. However, others tend to believe our data and not our theories: “No one but a theorist believes his theory; everyone puts faith in a laboratory result but the experimenter himself” [Galison, 2004, p. 69].) If one still believes the theory, then the next study should be designed to test the hypothesis in a new way and one hopes, provide clear results and also reconcile any conflicts.

Suppose, however, that one believes the data. There may be very good reasons for the conflicting results in studies, because the story may be more complex than originally thought. The conflicting results may, in fact, tell us something quite important about the cultural phenomena we are studying. Five very different examples hint at the wealth of possibilities:

1. A researcher finds that public behavior and cultural products tend to support a cultural norm X. However, in private attitude surveys, people do not seem to support norm X, and in fact support norm Y. It could be that for reasons previously discussed, attitude surveys just provide weaker results than analyses of behavior and collective representation. However, another possibility proposed by Miller and Prentice (1994) is that people may be in a state of “pluralistic ignorance.” Everyone in a culture may be against norm X but may think that everyone else supports norm X. As a consequence, people behave in ways consistent

with the norm, even when no one privately believes it. Miller and Prentice (1994, Miller, 1999; see also Sears & Funk, 1990) have provided examples of this involving norms about drinking, racial attitudes, and other topics, and Kuran (1995) has proposed pluralistic ignorance as one of the forces that sustained communism in Eastern Europe, apartheid in South Africa, and the caste system in India for so long.

2. As a variation of this, a researcher finds that attitudinal and behavioral data both support norm X, but the behavioral data are much stronger. Again, this could be because our attitude measures are simply weaker. However, there could be another, more important reason, namely, that many behaviors are *social* behaviors. *They necessarily involve other people and require their participation*, meaning that there will not be a simple linear relationship between a person's internal predispositions and the actions he or she produces.

Take a hypothetical example of two cultures that differ in the proportion of people who have an aggressive mind-set. Suppose that in Culture A 6% of the people have such a mind-set, whereas culture B has 2% of such people. Suppose further that interpersonal interactions follow something like an "it takes two to tango" rule (Daly & Wilson, 1988). In culture B, for any single encounter, there is a .04% chance that aggressive people will randomly meet and a fight will ensue. For culture A, however, there is a .36% chance of such people meeting and fighting. The three to one difference in attitudes has become a 9 to 1 difference in behavior, because the "two to tango" rule means that differences in behavior go up as a function of the square of the difference in attitude.

This effect is magnified further for any behavior that requires the meeting of three like minds. In this case, the 3 to 1 difference in attitudes becomes a 27 to 1 difference in behavior. More generally, the difference in behavior will go up as a function of d^n , where d is the ratio of the difference in attitudes, and n is the number of people of similar mind-sets that need to meet to produce the behavior.

The odds become further altered if one makes two reasonable assumptions: (1) that in various population landscapes people interact with similar others at rates either greater or less than what would be expected by chance alone, and (2) that people are not single-minded in

their approaches (e.g., "always act aggressively") but have a more complex set of decision rules that cover contingencies and give flexibility (e.g., "If I encounter a person of type X, then do A. If I encounter a person of type Y, then do B. If I encounter a person of type Z, then do C," and so on). In more complicated cases like these, game theoretical models and computer simulations can be of great help in thinking through how underlying distributions of attitudes in a population become translated into differences in behavior. The more general point for present purposes, however, is that differences between cultures in internal predispositions do not necessarily produce differences in behavior of the same magnitude, because social behaviors are some function of person A's disposition, person B's disposition, *and their interaction*.

3. A researcher conducts interviews and finds that all the people live in perpetual fear of their neighbors making violence against them. However, when she examines the public records, she finds that there has never been any violence in the community. This "paradox" is apparently not a terribly uncommon finding. The anthropologist Elizabeth Colson (1975, p. 37) writes:

We listen to informants' fears and to their tales of violence . . . and we diagnose a world of warring factions, of feud, of frequent acts of aggression. . . . We look around us, however, and we find people apparently behaving with kindness, generosity, and forbearance, avoiding disputes and sharing resources, tolerant of each other's foibles. What we may miss is the connection between the two sets of social facts: the beliefs are related to the behavior. . . . It should therefore be no surprise to us if some people live in what appears to be a Rousseauian paradise because they take a Hobbesian view of their situation: they walk softly because they believe it necessary not to offend others whom they regard as dangerous. (See also Adams, 2005; D. Cohen et al., 1999; Knauff, 1985; Fiske, Kitayama, Markus, & Nisbett, 1998.)

If one had done only the analysis of records or observed only the quotidian practices in the community, one might conclude the culture was a Rousseauian paradise. If one had done only the interviews, one might conclude it was a Hobbesian battleground. Neither results of interviews nor analysis of records is completely true, and both are an essential part of the story.

4. A researcher finds large cultural differences when examining laws and other collective products. However, when he examines individual behavior and attitudes, he finds that the differences are far less extreme. Perhaps then the big differences in collective products result from polarization effects that occur when groups form. Groups may become more extreme than the individuals in them because, during collective decision making processes, (a) people may engage in posturing to line up with a perceived cultural ideal (see item 1); (b) a particularly persuasive argument may carry the day during group discussions (Brown, 1965); or (c) the shared information to which all group members have access gets discussed far more often and gets far more weight than idiosyncratic information that individuals may possess (Stasser & Titus, 1985).

5. A researcher employs three different measures of a cultural trait *X*. All measures are face valid, yet none of the measures correlate with each other. It is possible that at least one of the measures is not in fact valid, and it is possible that the underlying theme *X* lies more in the researcher's mind than in cultural "reality."

However, consider another way of thinking about the cultural phenomenon. One crude metaphor for culture is culture as "a bag of tricks," or less pejoratively, as a "tool kit." There is no reason that all the tools or all the tricks related to cultural theme *X* have to be distributed equally among all members of the population. Some members of the culture have tool A, some have tool B, and some have tool C. This parallels a distinction Linton (1936) made about "core" cultural elements distributed to all cultural members and "specialized" elements that are distributed to different subgroups of the population. It also parallels the distributional approach to culture that, for example, Medin and Atran (2004; Medin et al., Chapter 25, this volume) take when they look for patterns of agreement among members of a culture or subculture.

Glazer (1957) discussed a related point in talking about the Jewish religion as a religion of practices rather than a religion of dogma (see also Dimont, 1978). Judaism does not have a central, unifying dogma; it does not have a central authority, and it emphasizes behaviors rather than beliefs (A. Cohen, Siegel, & Rozin, 2003). Instead of a central doctrine, there are loosely related practices and traditions. In modern secular society, Jews pick and

choose from among these traditions and practices (Glazer, 1957; also D. Cohen, 2007). Some Jews derive religious meaning by keeping kosher; others are observant by sending their children to Hebrew School; still others observe by saying daily prayers, and so on. (In addition, Glazer [1957, p. 142] points out that some derive religious meaning from acts that may not be overtly religious, such as "liking Yiddish jokes, supporting Israel, raising money for North African Jews, and preferring certain kinds of food"). If one were to do a factor analysis of practices and behaviors that are valid reflections of people's various ways of being Jewish, there might not be a massively dominant, tightly clustered factor that one could call "Jewish observancy."

The above merely represent five examples that are nonartifactual explanations for results that do not converge. There are many others that point to potentially interesting cultural phenomena. A researcher interested in such phenomena can devise follow-up studies to test his or her post hoc explanation for the current pattern of divergent data.

Summary

In summary, the interpretational issues facing cultural psychologists are many. The use of multiple methods makes for a convincing argument when the data converge across them. However, the data do not always converge. At that point, the researcher needs to figure out whether this lack of convergence is artifactual, or whether it is a hint that will lead to real, interesting, and important phenomena yet to be discovered.

A coherent social science explanation will also be strong in the way it integrates and differentiates. The researcher staring at the Necker cube of culture will discover how similarities are embedded within differences, and how differences are embedded within similarities. This similarity–difference perspective makes our field richer scientifically.

On Science, Poetry, and Policy

The similarity–difference perspective is also important for a very different reason. T. S. Eliot (1998) once wrote that good poetry makes the unfamiliar familiar and the familiar unfamiliar.¹² Melford Spiro (1990) appropriated this

observation to describe what anthropology was about. To make the unfamiliar familiar and the familiar unfamiliar by embedding differences within similarities and similarities within differences is good poetry. It is good science. And it is good policy. Ultimately, this familiar–unfamiliar, similarity–difference approach is what may prevent cultural psychology from degenerating into cultural stereotyping, or from being used as such. First, to the extent that we as a society come to see another group’s practices as similar to our own, we lessen the distance between us and the Other.

Second, to the extent that cultural psychology encourages people to step outside their own frames of reference, we soften our judgments of the Other. Cultural differences are real, and they will be noticed. (J. Cohen, 1988, defines a medium effect size as “visible to the naked eye” and many of our effect sizes are much larger than this). Given then that the differences will be noticed, how does one interpret them?

One can either (1) view the differences in terms of the dominant discourse, in which case comparisons with the Other are likely to be invidious, or (2) one can approach the difference by assuming (at least initially) that the difference reflects some meaningful, coherent way of seeing the world that is different from one’s own. Cultural psychology is about figuring out what those meaningful, coherent ways of seeing the world might be.

To deny that differences exist is to either assume that one’s own cultural values are universal (or will be universal, as soon as those other people “come around”). And to deny that the differences will be noticed is to assume that the world’s citizens are so dumb that they will never notice these differences that are “visible to the naked eye” in our increasingly pluralistic societies and interconnected world. Ultimately, one views differences through the prism of the dominant discourse, or one tries to study and understand the way other ways of seeing the world can be sensible, cogent, and meaningful. Cultural psychology does *not* imply a stance of moral relativism. (It does not imply that there are no moral standards; setting aside morality, it does not even imply that all cultural patterns are adaptive [see the section on Causation].) It does, however, imply a certain humility and urges us not to rush into either actions or judgments propelled by our own certitude (Fish, 2005; Shweder, 2003; Will, 2004b, 2005).

CONCLUSION

Researchers confront choices, because every method has its trade-offs. The methods themselves have assumptions built into them about what culture is. For example, they contain assumptions about how much we conceive of culture as being in the person versus “out there”; the methods contain assumptions about how readily cultural rules can be articulated, about what aggregates and collective products represent, and so on. Indeed, we make many assumptions by even thinking that a given cultural issue can be studied in some meaningful, tractable way.

As cultural researchers, we inherit all the problems of the disciplines in which we were trained, plus those that come with any attempt to understand, operationalize, sample, or interpret across cultures. We may face serious challenges, but working in our field also gives us some serious advantages. Cultural psychology is pluralistic in its methods, so its outlook is not limited by the use of a single paradigm or methodology. There is not yet, and I hope there never will be, a dogma to which cultural psychologists must adhere. And we are willing to listen to other fields, even if they are not (yet) willing to listen to us.

Finally, there is still plenty of “low-hanging fruit” for us to pick. Substantively, there are whole areas of the world yet to be explored by cultural psychologists, and a huge range of topics yet to be studied. Methodologically, the field is open for the discovery of new techniques and innovative ways of thinking about problems. The challenges we face and the opportunities we have are two sides of the same coin. If cultural psychologists have yet to find good answers to some of our methodological issues, it is because the field is still young. However, this same youth makes our field open, pluralistic, and full of opportunities.

NOTES

1. *Mind-sets* is used as a catch-all term: The prime may be doing a number of things, including activating scripts, making certain framings of a situation more accessible, activating different parts of the self-concept, and so on.

2. A mediational analysis does not have to involve a *chronic* individual difference; a mediation variable can also be a measurement of a temporary state or process (Smith & Bond, 2003). For an interesting and thought-

ful critique of mediation, see Spencer, Zanna, and Fong (2005), who advocate *manipulating* variables and finding moderators, rather than trying to measure mediators.

3. There is essentially a Zeno's paradox of mediation; that is, for any given causal connection, one can ask "What mediates this connection?" Thus, C may mediate the relation between A and B. One can then ask, "What mediates the connection between A and C (or B and C)?" If D mediates the connection between A and C, one can then ask "What mediates the connection between A and D (or between D and C)?" and so on. The example in the text assumes that this problem has been temporarily solved by temporarily accepting an individualistic or collectivistic orientation as being at an appropriate level of explanation.

4. More qualitative research would probably flesh out these prototypical situations, elaborate on scripts and rituals that accompany them, and describe them in terms of *practices*. Such work would likely take place outside the lab.

5. One might consider any difference between two cultural groups as definitionally a "cultural" difference. However, this chapter sticks with more conventional notions that there would be some differences that one would not want to call "cultural," and thus, there is a continuum of differences that run from "more cultural" to "less cultural."

6. If one were primarily focusing one's study on the relationship between crop volatility and fatalism, one might want to gather data from multiple countries that differed widely in the volatility of the crops they grew. However, for the sake of this example, pretend that for reasons discussed in the section on causation, the researcher wanted to focus in on these two cultures.

7. This sort of priming (the priming of cultural icons) and the priming described in the section on social cognitive approaches to culture are similar, in that they both demonstrate how flexible people can be in applying cultural schemas. However, the two types of priming lead to different sorts of inferences. Social cognitive priming is aimed at showing how a specific mind-set, implicit theory, or belief causes a behavior. In contrast, bicultural priming generally does *not* pinpoint a specific mind-set. Instead, bicultural priming tries to activate a very general mind-set—the worldview of "being Chinese" or "being American" for Chinese Americans, for example.

Social-cognitive priming and cultural icon priming may elicit either prime main effects or prime \times culture of participant interactions. Such prime \times culture interactions usually come in one of two forms. One might be called a *potentiating* prime and the other a *compensatory* prime. The logic behind a compensatory prime is that the prime will temporarily make accessible in culture A what is chronically accessible in culture B. Thus, for example, Heine et al. (2001) showed that priming European Americans with an incremental theory of ability makes them persist more on tasks, whereas it has no effect on Asians, who presumably already hold an incre-

mental theory as their default, chronically accessible theory. A *potentiating* prime, on the other hand, works on a very different principle, evoking a response from participants who are already "prepared" for the prime. Thus, Leung and Cohen (2007) found that an honor prime elicited the relevant honorable behaviors only among participants who were from cultures of honor (Southerners and Latinos). It did not have this effect for participants from other groups. The *potentiating* prime draws forth the prepared response from the honor group, but it has no effect on the other groups, because one cannot prime—or cannot *easily* prime—what is not there.

The cultural icon priming of Hong et al. (2000) follows the logic of a potentiating prime. A Chinese icon may draw forth a more "Chinese" response from a bicultural Asian American or Hong Kong resident, but it presumably would have little effect on a European American, who has no Asian identity to evoke (but cf. Bargh, Chen, & Burrows, 1996; Dijksterhuis & van Knippenberg, 1998; Kwan, 2007).

The compensatory versus potentiating prime distinction may be conceptually useful. However, some practical issues make the distinction blurry. Whether a prime potentiates a response depends not only on (1) how "prepared" the participants are with the accessible and relevant scripts and schemas but also on (2) how powerful the prime is. Thus, a relatively weak prime (e.g., a scrambled sentence task with words like *revenge* and *payback*) may act as a potentiating prime, calling forth a response only among those well prepared for a revenge mind-set. On the other hand, a 6-hour filmfest of revenge clips from John Wayne westerns, Charles Bronson *Death Wish* films, and the Arnold Schwarzenegger *Terminator* series may produce either a priming main effect (that shifts everyone) or a compensatory prime effect (if one group is already at ceiling). Because of cases like this, the logic of a potentiating prime ("One cannot prime what isn't there") might be modified to "One cannot easily prime what is not easily accessible."

8. For discussion of operationalization issues relevant to biological measures, see also Chiao and Ambady, Chapter 9; Levenson, Soto, and Pole, Chapter 32, both this volume; Tsai, Levenson, and McCoy, 2006.

9. Clinton explained the interpretation of "is" when talking about why he denied having sexual relations with a White House intern. "It depends on what the meaning of the word *is* is. . . . If *is* means *is* and never has been . . . that is one thing. . . . Now, if someone had asked me on that day, are you having any kind of sexual relations . . . that is, asked me a question in the present tense, I would have said no. And it would have been completely true" (Starr, 1998, footnote 1128). (Fortunately, the debate over whether Clinton lied never got to the point about whether *is* meant "Are you having sexual relations this very second?" However, further debate did center on the terms "sex" and "sexual relations," concerning what acts were covered under these expressions.)

10. The point can be taken too far. Sociologist Stanley Presser tells the story of his meetings with the famous survey sampling expert Leslie Kish. "How are you doing?" Presser would ask. "Compared to whom?" Kish would reply (MacFarquahar, 2004).

11. Thorough debriefings are especially important in culture research. Not only do some situations fail to translate but so also may the entire "frame" of the study—the conducting of a psychological experiment (Gintis, 2005). The "frame" of most laboratory psychology experiments is well understood by introductory psychology students: One goes to a room and performs some relatively innocuous task (possibly related to the experimental cover story, possibly not). In return, the experimenter gives you something of value that is relatively meaningless to him or her (either course credits or money from some deep pockets somewhere).

Henrich et al. (2001) found that this is not a universal script when they had members of various small-scale societies play economic games. (In one case, a respondent tried to attack the experimenter with a knife "because she thought he was an evil magician"; in another case, a rich herder in Mongolia refused to play because he did not want to take money away from the impoverished graduate student conducting the study; Gintis, 2005, personal communication, 2005).

12. Eliot's (1998, p. 108) exact quote was that good poetry makes "the familiar strange and the strange familiar," a notion he attributed to Coleridge.

CHAPTER 9

Cultural Neuroscience

Parsing Universality and Diversity across Levels of Analysis

JOAN Y. CHIAO
NALINI AMBADY

The existence of human diversity has been a source of contemplation and curiosity since the beginning of human history. In his encyclopedia *Etymologiae*, published in the seventh century, Isidori of Seville observed that diversity among humans existed not only in their appearance, such as color or body size, but also in the content of their minds (Jahoda, 2002). Philosophers, such as Descartes and Locke, continued speculation on the nature and origin of human diversity, introducing more formalized notions of culture and its relation to human nature into the lexicon. The study of culture and its role in humanity gained further prominence with the emergence of the field of anthropology in the late 19th century, which emphasized the study of cultural variation through observation of the customs, practices, values, and beliefs of different cultural groups, and later with the field of cultural psychology, which sought to apply the methodology of psychology and its emphasis on the individual mind to the study of cultural variation.

Contemporary cultural psychologists have made considerable progress in documenting

cultural variation in human thought and action. The mutual constitution of culture and mind has been demonstrated in a variety of fundamental psychological processes, including the way people conceive of the self (Markus & Kitayama, 1991; Markus, Kitayama, & Heiman, 1996), how they make causal attributions (Morris & Peng, 1994), how they attend to and remember objects in their environment (Miyamoto & Kitayama, 2002; Kitayama, Duffy, Kawamura, & Larsen, 2003; Masuda & Nisbett, 2001), and how they perceive, experience, respond to, and predict their own and others' emotions (Elfenbein & Ambady, 2002; Lam, Buehler, McFarland, Ross, & Cheung, 2005; Mesquita & Frijda, 1992). A fundamental assumption of this research is that the human mind is intimately linked with its social world or cultural context, and that culture is continuously created through the actions and products of the individual minds that comprise it.

Cultural psychologists have been wary, however, about integrating biological perspectives into their research endeavors, perhaps because

they assume that investigations into the biological bases of the mind reflect an empirical search for human universals rather than cultural differences (Norenzayan & Heine, 2005; Smedley & Smedley, 2005). Likewise, cognitive neuroscientists have viewed their discipline as a pursuit of universal truths rather than culturally specified instances about how the brain gives rise to the mind and vice versa (Kosslyn, 1999). Yet a growing number of studies show that both the structure and the function of the developing human brain is shaped both by the environment and by cultural experiences (Johnson & Munakata, 2005). Moreover, although recent advances in human genomics and molecular biology demonstrate that whereas the majority of the human genome is conserved across human cultures, variation in the frequency of different genes does exist between different human populations. This variation of genes between cultures suggests that cultural variation may emerge at multiple levels, possibly as a result of interactions between levels (e.g., gene–brain, culture–behavior, culture–gene, culture–brain–gene; Bonham, Warshauer-Baker, & Collins, 2005). Thus, we argue that cultural psychologists’ notions of the “mutual constitution” of culture and mind needs to be broadened beyond interactions between culture and the mind, to interactions among culture, genes, and the brain.

Early articulations of this idea of bidirectional influences among culture, genes, mind, and the brain can be traced to the work of prominent developmental psychologists such as D’Arcy Thompson and C. Waddington, who laid down the original framework for what would later come to be known as *probabilistic epigenesis* (Johnson, 1997). According to this view, humans come into the world with sets of possible developmental trajectories (each with their own alternative end states, presumably described by the genome) that are then pursued, or not, over the course of development as a result of interactions with environmental input. The notion of *biocultural co-constructivism* was introduced more recently to account for the significance of plasticity across development in gene–environment interactions; humans may come into the world with a set of possible developmental trajectories, but once on a certain trajectory, plasticity may alter both the path and the end state (Li, 2003, Chapter 21, this volume). The empirical challenge brought on by both views is finding ways

to articulate precisely how neural mechanisms and psychological capacities emerge through complex, multilevel interactions between genetic forces and the cultural environment.

To designate an approach to meet this challenge, we introduce in this chapter the term “cultural neuroscience,” which is a theoretical and empirical approach to investigate and characterize the mechanisms by which this hypothesized bidirectional, mutual constitution of culture, brain, and genes occurs. Specifically, we suggest that biological factors may lead to cultural variation at the neural and genetic levels, and that cultural factors may lead to variation in brain structure and function, as well as gene expression. To accomplish this, we first focus on identifying the conceptual landscape covered by the term “cultural neuroscience.” Second, we describe the methodological toolbox needed for accomplishing cultural neuroscience research. Third, we review recent progress in identifying cultural variation at the genetic and neural levels. Fourth, we discuss the nature and meaning of cultural variation across different levels of analyses. Finally, we identify important challenges and considerations that need to be addressed for cultural neuroscience to progress systematically and significantly.

CULTURAL NEUROSCIENCE: DEFINING THE LANDSCAPE

Cultural neuroscience is an area of research that investigates cultural variation in psychological, neural, and genomic processes as a means of articulating the interrelationship of these processes and their emergent properties (see Figure 9.1). A multilevel analytic approach to studying psychological phenomena and human behavior has become more popular, as demonstrated by the number of subfields that have proliferated in recent years, each incorporating neuroscience into a parent social science discipline; these include social neuroscience (Cacioppo, Lorig, Nusbaum, & Berntson, 2004), social-cognitive neuroscience (Ochsner & Lieberman, 2001), affective neuroscience (Davidson, 2003), and neuroeconomics (McCabe, 2003). Whereas cultural neuroscience shares the goal of these subfields to explain a given phenomenon in terms of an emergent property of interactions between mental and neural events, cultural neuroscience is distinctive in that it focuses squarely on examin-

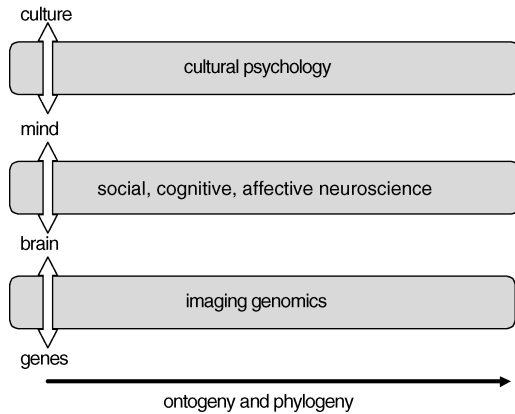

FIGURE 9.1. Diagram of the cultural neuroscience framework.

ing psychological and neural processes that may vary across cultural groups in some meaningful way. Cultural neuroscience can be seen as a complementary endeavor to evolutionary psychology (see review by Cosmides, Tooby, & Barkow, 1992); however, whereas evolutionary psychology seeks to articulate the universal, evolved architecture of the mind shared by all humans, cultural neuroscience emphasizes cultural variation, specifically, investigating interactions between events at the psychological, neural, and genetic levels.

The Neuroscience of Culture versus Race

The goals and research questions of cultural neuroscience are to a certain extent similar to those driving the modern neuroscientific study of race. In recent years, the importance of social experience on brain function has been highlighted by studies showing that racial group membership affects neural processes underlying other basic aspects of social cognition, such as face perception and recognition, as well as social evaluation and bias (see Eberhardt, 2005, for a review). Work in this area has been groundbreaking in demonstrating how racial group membership (and racial experience more generally) can modulate the neural activity underlying basic perceptual and cognitive processes. Cultural neuroscience, however, is likely to illuminate how sociocultural and biological factors influence each other in ways not previously revealed by neuroscientific studies of race. Culture and race differ in a number of important respects (Betancourt & Lopez, 1993).

Culture refers to shared meaning systems, social practices, geographical space, social and religious values, language, ways of relating, diet, and ecology (Markus et al., 1996). In contrast, the concept of race, which typically refers to physical characteristics such as skin color, facial features, and hair type shared by people of a given ancestral origin, is shrouded in controversy about whether “race” refers solely to biological or socially constructed features that differentiate groups of people (Bonham et al., 2005; Smedley & Smedley, 2005). Individuals may belong to different races but may share the same culture. Whites, blacks, Hispanics, and Asians living in America, for example, share the same government structure and, to some extent, the same language, ecology, social values, and ways of relating, but are considered members of different racial groups. When neuroscience investigations of race and brain function include participants from the same culture (which, to date, all studies have), they do not capture how different meaning systems (e.g., collectivism and individualism), languages (e.g., Chinese and English), ways of reasoning (e.g., dialectism), and so on, may arise from, as well as alter, neural processing and genomic expression.

The suggestion that broad phenomena such as culture can be understood in terms of interactions between multilevel events (e.g., neural, situational, genetic) may be construed as a form of reductionism and may therefore be subject to criticisms typically associated with reductionist agendas. Philosophers of science and scientists of all kinds have long grappled with the problem of whether complex phenomena, such as consciousness, are truly reducible to their component parts (Dennett, 1995; Nagel, 1998). For instance, does reducing the phenomenon of consciousness into a description of neural events somehow fail to capture the context within which consciousness occurs, and do the phenomena that emerge from these neural events differ from the actual events themselves? The aim of cultural neuroscience is *not* to “reduce” culture into a description of genetic and neural processes at the expense of the characterization of emergent properties, nor is it intended to replace the language of culture with the language of neurons or molecules. The goal of a cultural neuroscience approach is empirically to shed light on the extent to which the cultural variation observable in human behavior and mental life is traceable to cultural

variation at other levels of analysis and their interaction, including the biological and neural levels.

THE CULTURAL NEUROSCIENCE TOOL BOX: INTEGRATING METHODOLOGIES

What makes the study of cultural neuroscience a more viable empirical and theoretical proposition for modern scientists is the amalgamation of recent methodological advances in the fields of cultural psychology, cognitive neuroscience, and molecular biology. In recent years, cultural psychologists have made significant advances in articulating the criteria for creating culturally appropriate behavioral measures that ensure the psychological phenomenon of interest is testable in people of all cultures (Norenzayan & Heine, 2005). Cognitive neuroscience has revolutionized the study of the mind and brain by developing an arsenal of techniques for mapping neural structures to psychological functions at varying degrees of spatial and temporal resolution (Gazzaniga, Ivry, & Mangun, 2002; Handy, 2005; Heeger & Ress, 2002). Molecular biology has seen rapid transformation in recent years with the development of tools for enabling the efficient and economical translation of the human genome (Hariri & Weinberger, 2003). Taken together, the convergence of these tools enables the unprecedented ability to investigate the mutual constitution of genes, brain, behavior, mind, and culture (see Figure 9.2).

Behavioral Paradigms

The first important tool in the cultural neuroscience tool box is a compilation of *behavioral paradigms* appropriate for examining cognitive, perceptual, emotional, and social-cognitive phenomena in people of different cultures. The development of cross-culturally sensitive behavioral paradigms has proved challenging in several regards. The ways that tasks are created and administered may favor one cultural group over another in ease and intuitiveness; specifically, cultural differences may exist in response styles where people of certain cultures are more comfortable with completing questionnaires relative to others (Greenfield, 1997). Participants of certain cultures may be more likely to use the center rather than the extremities of a scale in a questionnaire (Chen, Lee, & Stevenson, 1995). Free-response formats requiring extensive translation may produce errors in meaning; such errors may also arise when translating the instructions of measures from one language to another (Brislin, 1970). Responses associated with demand characteristics may be more frequent when sampling from cultures that value “saving face” above accurate self-report (Heine, Takata, & Lehman, 2000), and culture may affect the different social referents used when providing self-reports (Heine, Lehman, Peng, & Greenholtz, 2002). Psychologists have created a number of solutions to these methodological worries, including back-translation (Brislin, 1970), incorporating different kinds of behavioral measures in a study (Nisbett & Cohen, 1996), and even using hidden behavioral measures (Heine et al., 2000).

Convergent Neuroscience Methods

The second component of the cultural neuroscience tool box is *convergent neuroscientific methods* for characterizing the neural processes underlying a given psychological function. There are several neuroscience tools available to psychologists interested in mapping neural structure to mental function, including functional MRI (fMRI), positron emission topography (PET), transcranial magnetic stimulation (TMS), magnetoencephalography (MEG), and event-related potentials (ERPs); each tool has its strengths and weaknesses (Gazzaniga et al., 2002). Imaging techniques, for example, such as fMRI and PET have very good spatial reso-

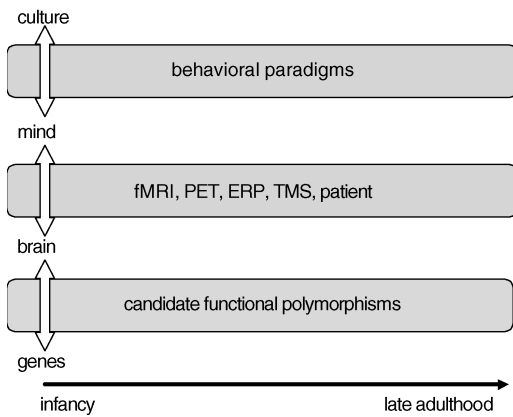

FIGURE 9.2. Diagram of the cultural neuroscience tool box.

lution (in cubic millimeters) and are crucial to identifying which brain regions are involved in different aspects of processing (Heeger & Ress, 2002). However, because they record differences in blood flow, which occurs on the level of seconds, and not neural activity directly, which occurs on the level of milliseconds, imaging techniques lack temporal precision. Cortical recording techniques, such as the ERP, are extremely temporally precise, because they directly record neural activity to the precision of milliseconds and are therefore good for determining when a process is occurring or when a difference in neural processing emerges (Handy, 2005). Unlike fMRI and PET, the ERP lacks spatial precision, because it records electrical signals only from cortical regions directly under the scalp. This is particularly problematic for the study of subcortical areas, such as the amygdala, that have been strongly implicated in the processing of emotions. MEG, a methodology with both the advantages of brain imaging techniques and ERPs directly records electrical activity from the brain, thus having extremely high temporal resolution. MEG also has good spatial resolution due to the high number (e.g., approximately 300 channels) and sensitivity of the channels used to record electrical activity.

TMS and studies of patients with brain lesions are currently the only way of discerning which regions in a normal brain are *necessary* for performing a certain function, such as recognizing faces or emotional expressions. TMS uses rapidly changing magnetic fields to induce electric fields in a specific brain region and can be applied repetitively (Paulus, Hallett, Rossini, & Rothwell, 1999). In a typical TMS experiment, a powerful magnet that is held over a cortical region of the brain (e.g., the motor cortex or frontal gyri) delivers magnetic pulses for a few minutes. The application of these magnetic pulses affects electrical and biochemical activity in the directed brain region and in interconnected brain regions. Typically, the region in which TMS is applied undergoes suppression of activity or temporary dysfunction, creating a “temporary functional lesion.” If this neural dysfunction is accompanied by behavioral decline, one can infer that a given brain region is *necessary* for a particular mental function. Similarly, by testing a given behavioral paradigm in patients with discrete brain lesions, one can infer whether or not a brain region is *necessary* to produce a certain behavior.

Disadvantages of patient studies are that lesion sites rarely completely overlap nor is severity of brain damage identical across patients. Such heterogeneity in location and severity of brain lesions may affect the degree to which one can infer that a specific area of the brain is critical. Thus, the advantage of TMS is that one can examine the necessity of a given neural structure within the same location across several normal brains.

Given their different strengths and weaknesses, no individual neuroscientific method can independently capture the rich complexity with which the brain processes cognitive and emotional information. Rather, it is the convergence of findings from multiple techniques that enables us to make sound inferences about neural structures and their psychological function. ERPs tell us when neural processes are occurring. MRI and fMRI provide information about the structure and function of the human brain. TMS and patient populations provide information about whether a given brain region is necessary for a given psychological function.

Genes and Their Functional Polymorphisms

Genes, the fundamental physical and functional unit of heredity, substantially influence every level of human biology, including neural function and mental processes. Genes are thought to account for a majority of psychiatric illnesses, prompting many studies that attempt to map specific genes onto various cognitive, emotional, and personality styles and disorders (Hariri & Weinberger, 2003). The entire human genome comprises a relatively small number of unique genes, approximately 20,000 to 30,000, many of which are found in the genomes of other species, from simple organisms, such as bacteria and fruit flies, to more complex ones, such as sheep and monkeys (Cavalli-Sforza, 2005). Although the actual number of genes is small, individual genes can take on various forms, known as polymorphisms, that result from evolutionary “mistakes” whereby the original genetic structure is modified in small but significant ways: through snips, repeats, and deletions of base pairs. There are approximately 3 million polymorphic variation sites in the human genome, and it is the variation in these sites across populations and subpopulations that has yielded surprising and potent insights into the possible origins of psychological and neural differences

across individuals and cultures (Cavalli-Sforza, 1998, 2005).

Hence, the third part of the cultural neuroscience tool box is a means of determining the presence or absence of functional polymorphisms and their variants in an individual. Identifying functional polymorphisms is important to designing experiments that test whether a given neural or mental process is influenced by one's genome. Blood samples and cheek swabs are the primary ways of obtaining DNA from individuals; body samples are then amplified through polymerase chain reactions (PCRs) tailored to isolate specific functional polymorphisms (Gelernter, Kranzler, & Cubells, 1997). Once the variants of a given polymorphism in an individual is identified (e.g., short or long allele carrier), they can then be separated into different groups and the participant's neural and psychological responses can be compared in light of his or her genomic profile.

These three basic components of the cultural neuroscience tool box—(1) culturally appropriate behavioral paradigms, (2) neuroscience tools, and (3) functional polymorphisms—offer an unprecedented amount of experimental power for cross-level analyses of cultural variation. These tools allow the measurement of individual mental, neural, and genomic information, and comparisons of individuals from different cultures at every level. A multilevel analysis has long been considered necessary for a full articulation of the mutual constitution of culture and the mind; the unification of novel experimental techniques in the cultural neuroscience tool box described earlier provides the means to achieve this. As existing tools improve and new tools are introduced, the tool box will need to be updated and refined.

CULTURAL VARIATION IN BEHAVIOR

Numerous behavioral studies, mostly comparing Easterners (e.g., Chinese, Japanese) and Westerners (e.g., Western Europeans, European Americans), suggest that there is significant cultural variation in basic psychological processes, including mathematical thinking, reasoning style, memory, emotion, and the self (see review, in Markus & Kitayama, 1991; Nisbett & Norenzayan, 2002). For example, Mandarin speakers talk about time as if it were vertical,

whereas English speakers refer to it as horizontal (Boroditsky, 2001). Easterners tend to attend to the background or situation, whereas Westerners focus on the object within a scene (Masuda & Nisbett, 2001). Furthermore, Easterners tend to perceive objects and people, and the situation in which they are embedded as mutually interdependent; thus, they may use holistic strategies for perceiving people and scenes. Westerners, however, who are more likely to perceive objects and people as independent from the situation, apply a more analytic strategy for perceiving entities in their environment (Nisbett & Norenzayan, 2002). These examples provide a window into the degree to which culture shapes basic psychological processing and serve as a foundation for research that examines cultural variation at other levels of analysis, including genes and the brain. Because behavioral findings that document cultural variation in mind and behavior are well represented in other chapters, we focus our discussion on cultural variation beyond behavior.

CULTURAL VARIATION IN THE BRAIN

The vast majority of cognitive neuroscience research has focused on elucidating functional relationships among brain, mind, and behavior, which are presumed invariant across cultures (Plomin & Kosslyn, 2001). However, there are several reasons to suspect meaningful cultural variation in brain structure and function. First, as discussed earlier, there seems to be significant cultural variation in functional polymorphisms associated with primary cognitive and affective capacities. Furthermore, approximately 70% of genes are expressed in the brain. Thus, cultural variation in brain function is possible to the extent that these functional polymorphisms affect efficiency and capacity of neurotransmission (Hariri & Weinberger, 2003). Second, experience, particularly perceptual or social experience during certain periods of development, can play a definitive and shaping role in the acquisition and maturation of neural mechanisms underlying a wide range of fundamental skills, including language (Neville & Bavelier, 1998), music comprehension (Janata & Grafton, 2003), face processing (Gauthier & Nelson, 2001), and spatial navigation (Wolbers, Weiller, & Buchel,

2004; Maguire et al., 2000). To the extent that cultural rules, values, beliefs, and practices shape perceptual and social experience, and to the extent that experience differs between cultures, cultural differences in neural responses underlying cognitive and affective processes are likely to exist (Park & Gutchess, 2002). Third, behavioral research suggests significant cultural variation, particularly between Westerners and East Asians, in their basic perceptual, cognitive, and affective strategies, that may have emerged as a result of divergent philosophical and reasoning traditions (e.g., holistic vs. analytic) between the East and West (Nisbett, Peng, Choi, & Norenzayan, 2001). To the extent that neural mechanisms underlie psychological ones, we would expect to find differences in neural activity for psychological functions where notable behavioral differences exist between cultures. Finally, the neural bases of a given mental function may vary across cultural groups either in terms of structures and circuitry recruited to perform a given task (e.g., to recognize emotions or colors) or the degree to which these structures are activated during the task, even in absence of observable behavioral or genetic differences. Thus, investigating cultural variation in brain structure and function is both a viable and necessary endeavor for fulfilling the goals of both cultural psychology (e.g., to articulate meaningful cultural differences) and cognitive neuroscience (e.g., to identify and explain brain structure and function).

Despite notable progress in describing cultural variation at the behavioral and genetic levels in recent years, still relatively little is known about the ways the structure and function of the human brain vary across different cultures. To date, the lion's share of empirical research on cross-cultural differences in the brain has been in the domain of language (e.g., the neural bases for cross-linguistic differences and multilingualism; Paulesu et al., 2000; Bolger, Perfetti, & Schneider, 2005; Xue, Chen, Jun, & Dong, 2006). Empirical progress in investigation of cross-cultural differences in neural activity for a broader range of psychological phenomena, from object perception (Ketay, Hedden, Aron, Markus, & Gabrieli, 2005) and theory of mind (Kobayashi & Temple, 2004) to music (Morrison, Demorest, Aylward, Cramer, & Maravilla, 2003) and taste perception (McClure et al., 2004), is also growing rapidly.

CULTURAL VARIATION IN THE HUMAN GENOME

Incredible controversy has ensued in recent years over the question of whether racial or cultural differences exist at the level of the human genome and if it even makes sense to apply concepts such as race and culture to the genome (Sankar & Cho, 2002; Wang & Sue, 2005). Such controversy is not without merits. The human genome is incredibly conserved, with only approximately 0.2% to 0.4% of the genome varying across individuals (Tishkoff & Kidd, 2004). Mutation, migration, genetic drift, and selection are all sources of normal genetic variation in cultures (Cavalli-Sforza, 1998, 2005). Individual genomic variation accounts for approximately 90% of total genomic variation. There also exists variation in genes at the population level, but on a much smaller scale, because people are more likely to mate with others who live close to them, and to share the same language and phenotypic qualities (e.g., assortative mating; Tishkoff & Kidd, 2004; Wang & Sue, 2005). Given that the majority of the genome does not appear to vary across cultural groups or populations, does it even make sense to pay attention to cultural variation in genomic frequencies?

We argue that although it occurs on a much smaller scale relative to individual genetic variation, genomic variation at the population level should not be ignored; instead, it should be considered seriously, with scientific rigor and ethical care. We prefer to discuss population variation in the genome in terms of culture rather than race, because culture refers not only to ethnic heritages and phenotypic similarities between individuals but, perhaps more importantly, also to shared lifestyles, diet, geographical region, and other environmental aspects that likely have a significant interaction with brain function, gene expression, and selection. Both the sheer range of genomic frequency variation in the number of genes that demonstrate group frequency variation and the number of cultural groups for which frequency distribution differs are impressive, posing a formidable challenge for molecular biology research (Cheung et al., 2000). Indeed, molecular biologists have designed online databases (e.g., ALFRED¹) on the Web to facilitate public dissemination of catalogues documenting variation in genomic frequencies for populations all over the world: from the Khung San tribe in Af-

rica to the Yemenites in Eastern Europe (Osier et al., 2002). Although it is possible that cultural variation in allelic frequency for many genes will not have direct functional consequences on the mind or brain, there is growing evidence to the contrary. Here, we highlight two functional polymorphisms, *DRD4* and *5-HTT*, with significant cultural variation in genomic frequencies that has already been demonstrated to influence psychological and neural mechanism substantially.

***DRD4*: Dopamine Regulator Gene**

The dopamine receptor gene, *DRD4*, is one of the most polymorphic genes. Variants of the *DRD4* vary in the number of imperfect 48 base pair (bp) tandem repeats, ranging from 2 to 11 repeat units, but most commonly 4 to 7 repeats. The number of repeat units on the *DRD4* affects the size of the dopamine receptor and its ability to bind to dopamine-like molecules (Benjamin et al., 1996). Variation of the *DRD4* gene has been linked to novelty-seeking behavior and psychiatric disorders (Gelernter, Kranzler, Coccaro, et al., 1997). Considerable evidence suggests that the seven-repeat *DRD4* variant is involved with increased novelty-seeking, risk-taking behavior and hyperactivity (see review by Munafo et al., 2003). The frequency of long versus short-allele carriers of the *DRD4* gene varies significantly across cultures. A low proportion of the East Asian population carries the long-allele variant of *DRD4* (e.g., 1% carry seven repeats), whereas an extremely high proportion of the South American Indian population carries the long-allele version (e.g., 78% carry seven repeats; Chen, Burton, Greenberger, & Dmitrieva, 1999).

There are several possible explanations for this cultural variation in the genome. One is the *founder's effect*, whereby a higher proportion of long alleles within a migratory population may be due to the fact that founders of that population migrated as a behavioral consequence of carrying the long allele of the *DRD4*, which promoted exploratory behavior. A second possibility is *natural selection*, whereby South Americans carrying the long allele had an advantage relative to their short-allele-carrying counterparts, thus providing them with a reproductive/survival advantage. A third hypothesis is *random mutation*, whereby frequency differences in long- versus short-allele versions of *DRD4* within a small population

result from spontaneous mutation, such that over each successive generation, by chance, long-allele individuals leave more descendants relative to short-allele individuals, which then leads to a reduction in heterogeneous genetic variation within that population over time.

Chen and colleagues (1999) conducted regression analyses to determine the factor(s) driving the variation of *DRD4* between East Asians and South American Indians. In particular, they compiled existing data on *DRD4* allele frequencies of 2,320 individuals from 39 populations, and on the long-term migration pattern (e.g., 1,000 to 30,000 years ago) for these populations. They found that populations known to migrate had a significantly larger proportion of individuals with the long allele of the *DRD4* relative to nonmigratory populations. Chen and colleagues speculate that this association is not due to founder's effects, because the rate of long alleles of *DRD4* is identical for immigrants (e.g., Chinese and Japanese immigrants in the United States) and their respective comparison group (e.g., Chinese in China and Japanese in Japan). This suggests that the increased rate of long alleles among migratory groups more likely resulted from adaptation to the challenges of migration rather than to a particular subset of individuals who founded the migratory groups. Future research is needed to determine whether the striking cultural variation in *DRD4* allele frequency between East Asian and South American populations corresponds with cultural variation in neural mechanisms underlying novelty-seeking behavior, risk taking, or hyperactivity.

***5-HTT*: Serotonin Regulator Gene**

The serotonergic uptake transporter gene, *5-HTT*, is another polymorphism known for cultural variation. *5-HTT* codes for proteins that regulate the reuptake of serotonin at brain synapses and plays a critical role in the regulation of emotional processes. Similar to variants of the *DRD4* gene that differ in length, the two main variants of the *5-HTT* gene, short (*s/s*) and long (*l/l*), differ in the length of the promoter region that subsequently affects when, where, and how much protein is made. The long allele of the *5-HTT* is associated with higher transcription efficiency relative to the short allele, ultimately promoting higher levels of serotonin in the synapse.

Behavioral genetics studies examining the functional role of *5-HTT* in emotion have found that individuals carrying the short allele were slightly more prone to abnormal levels of anxiety relative to long-allele carriers (Lesch et al., 1996), a finding later corroborated by others (Katsuragi et al., 1999; see review by Sen, Burmeister, & Ghosh, 2004). People with the short allele were also found to acquire conditioned fear responses more readily than those without this allele (Garpenstrand, Annas, Ekblom, Orelund, & Fredrikson, 2001). Finally, a study by Caspi and colleagues (2003) showed that individuals with the short allele for this gene were more susceptible to stressful life events and twice as likely to suffer from depressive symptoms, diagnosable depression, and suicidality compared to individuals with the long allele.

Further evidence for a critical role of *5-HTT* in emotion processing comes from imaging genomics research examining the relationship between *5-HTT* and brain function. In particular, recent work has linked the *5-HTT* serotonin uptake gene to amygdalar function. A recent imaging genomics study by Hariri and colleagues (2002) demonstrated that individuals with the short allele showed greater amygdalar activation during an emotion-matching task relative to individuals with the long allele. Another imaging study by Furmark and colleagues (2004) found enhanced right amygdalar response in social phobics with one or two copies of the short allele compared to social phobics who were homozygous for the long allele during anxiety provocation. Greater amygdalar reactivity in response to emotional stimuli in short-allele carriers relative to long-allele carriers may underlie their heightened sensitivity or arousal to emotional stimuli, ultimately leading to higher rates of anxiety and depression disorders. These findings, though preliminary, are groundbreaking, because they show a direct relationship between genes and brain function, whereas previously researchers had only been able to study the relationship between genes and behavior. Moreover, examining the link between genes and brain function may prove more fruitful than studying the link between genes and behavior, because genetic variation in both studies accounted for more than 20% of variance in brain function even though no differences in behavioral measures (e.g., emotion matching task) emerged between the short- and long-allele groups in these particular studies.

Critically, Japanese and Caucasians from Western Europe and the United States significantly differ in the number of individuals within the cultural group that carry the short versus long allele of the *5-HTT* genotype. Several behavioral genetics studies have reported that in a typical Japanese sample, 70–80% of individuals carry the short allele (*s/s* or *s/l*) compared to 20–30% of individuals carrying the long allele. In a typical Caucasian sample, 55–60% of individuals carry the long allele and only 40–45% of individuals are short-allele carriers of the *5-HTT* genotype (Gelernter, Kranzler, & Cubells, 1997; Gelernter, Kranzler, Coccaro, et al., 1997; Hariri & Weinberger, 2003). Several behavioral genetics research groups have also reported this cultural difference among independent samples of Japanese and Caucasians, further validating this potentially important finding (Kumakiri et al., 1999). A critical research direction for the future is to investigate the relationship between this cultural difference in frequency of short-versus long-allele carriers of *5-HTT* and cultural differences in behavioral performance on anxiety, personality or emotion measures, as well as brain functioning, such as in amygdalar reactivity to emotional stimuli (Chiao et al., 2004).

To the extent that *5-HTT* is relevant to normal and abnormal emotion processing, it is important to consider how and why Japanese and European populations differ so dramatically in their ratio of short- versus long-allele carriers and what implications this has for cultural differences in emotion at the neural and behavioral level.² Behavioral geneticists speculate that the population differences may reflect a combination of varying behavioral adaptation in different populations, adaptation related to other phenotypes, and genetic drift of another important but neutral polymorphism (Gelernter, Kranzler, & Cubells, 1997; Gelernter, Kranzler, Coccaro, Siever, & New, 1998). Whether this difference in frequency of short- versus long-allele carriers between Japanese and Caucasian populations drives the cultural variation in cognition and emotion observed at behavioral and neural levels is an intriguing question for future research.

Despite growing evidence that substantial variation in genomic frequencies exists across cultures, we are only beginning to understand its functional scope and the broader implications for explaining cultural variation in psy-

chological processes, brain structure, and function. Enthusiasm for this endeavor is to be met with caution, because scholars need not look too far back in history for examples of arguments whereby genomic differences across the races were documented as a means of justifying a racial hierarchy (Eberhardt, 2005; Fraser, 1995). As Gould (1981) and others have aptly cautioned, science does not operate solely in an objective vacuum but in the mosh pit of social, political, and historical ideologies and environments. Scientists should be aware of the moral issues at stake when conducting cultural neuroscience research and take responsibility to protect against potential misuse or misinterpretation of their findings by the lay public, media or naïve scholars.

Correspondence of Culture Variation across Levels of Analysis

One way that investigations of cultural differences in brain function may prove useful is to provide converging evidence that extends behavioral research to demonstrate cultural differences in cognitive, emotional, or perceptual abilities. A recent fMRI study comparing neural activity during the Framed Line Test (FLT) between East Asians living in the United States for less than 7 years and European Americans provides a compelling example (Ketay et al., 2005). Originally created by Kitayama and colleagues (2003), the FLT assesses one's capacity both to incorporate and to ignore contextual information in a nonsocial domain. In the original version of the FLT, participants are presented with a square frame with a vertical line embedded within it and are then shown another square frame of the same or different size. They are asked to draw a line that is either identical to the first line in the first square frame in absolute length (absolute condition) or proportionate to the height of the surrounding frame (relative condition). The absolute condition requires one to ignore the context (both the first and second frame) when reproducing the line, whereas the relative condition requires one to incorporate context when reproducing the line. Results from a previous behavioral study of the FLT showed that Asians were more accurate in the relative condition, whereas European Americans were more accurate in the absolute condition (Kitayama et al., 2003).

In the recent neuroimaging study of the FLT, participants performing a modified version of

the task viewed a series of stimuli, each comprising a line inside a square, both of which varied systematically in size across trials. Specifically, participants judged whether either (1) the proportional size of the line relative to the square was the same as the stimuli just seen in the previous trial (relative condition) or (2) the absolute length of the line, regardless of the square size, was the same (absolute condition). Results from this study revealed cultural variation in neural responses to the extent that certain brain regions were recruited to perform the relative and absolute line judgment tasks. East Asians demonstrated greater recruitment of the dorsolateral prefrontal cortex (DLPFC), a brain region important in working memory tasks, for absolute versus relative line judgments, whereas European Americans showed more engagement of the anterior cingulate cortex (ACC), a brain region typically engaged during cognitive conflict, for relative versus absolute line judgments. These fMRI results extend previous behavioral results showing that East Asians and European Americans use different cognitive strategies to perceive objects embedded within a background by demonstrating differential recruitment of neural circuitry during such perceptual judgments between cultural groups.

Culture Variation in Neural Systems

Cultural differences may also exist at the neural level, even in the absence of cultural differences in the behavioral level. For example, an fMRI study by Gutchess, Welsh, Boduroglu, and Park (2006) compared neural activation between East Asian Americans and European Americans as they performed unintentional encoding of a series of pictures of objects (e.g., elephant), backgrounds (e.g., beach) and objects embedded in meaningful backgrounds (e.g., elephant on a beach), and rated how pleasant they found the pictures (e.g., *pleasant*, *neutral*, or *unpleasant*). After scanning, participants were given a surprise recognition test. Ratings of pleasantness did not interact with the culture of participants. Moreover, East Asian Americans and European Americans performed equally well, suggesting that task difficulty was equivalent across the two groups of participants, but significant group differences emerged in recruitment of distinct brain regions. Specifically, European Americans activated more regions implicated in object pro-

cessing, including the bilateral middle temporal gyrus, left superior parietal/angular gyrus, and right superior temporal/supramarginal gyrus. These results suggest that people of different cultural groups may use different encoding strategies and recruit different neural systems, even though both groups perform on object recognition tasks with equivalent behavioral competence.

In a cross-cultural fMRI study conducted in our laboratory on the neural bases of emotion recognition, Japanese participants, living in Japan, and European American participants, living in the United States, were scanned while explicitly recognizing Japanese and European American happy, neutral, fearful, and angry facial expressions (Chiao et al., 2004). Behavioral results indicated that all participants recognized facial expressions in Japanese and European American faces equally well. However, neuroimaging results showed that more Japanese than European American participants recruited distinct neural networks while judging ingroup versus outgroup emotional expressions. Hence, cultural variation in how the brain processes information may exist even when cultural variation is not observable in behavior; thus, inquiry into cultural variation at the neural level has the serious potential to provide novel insight into the universality and cultural specificity of neural processing.

Culture as Experience

Another way that cultural differences at the neural level may emerge is in brain regions that are experience-dependent or experience-sensitive. Modulation in these regions reflects the degree of familiarity or exposure to a given type of stimulus or task and may be accompanied by heightened skill or proficiency in a given behavioral task. One example of this kind of cultural difference at the neural level comes from fMRI and ERP face recognition studies in adults, showing that activity in the fusiform gyrus differs for faces of different racial or cultural groups and may be moderated by degree of interracial exposure (Golby, Gabrieli, Chiao, & Eberhardt, 2001). Another example of the influence of musical expertise or familiarity on neural responses comes from studies comparing neural responses to music in professional musicians and in novices. Recent ERP research suggests that familiarity with a given musical instrument alters neural re-

sponses to that instrument's sound. In particular, Turkish listeners showed a greater P3 amplitude response to hearing music from a familiar instrument (e.g., *ney*) relative to an unfamiliar instrument (e.g., cello), suggesting that hearing familiar music increases the allocation of attentional resources during memory (Arikan et al., 1999). Moreover, Morrison and colleagues (2003) used fMRI to compare neural activity in professional musicians (expert) and novices (control) while they listened to music of their own (Western-familiar) versus other culture (Chinese-unfamiliar). They found no difference in neural responses during listening to Western versus Chinese music in either music experts or novices, supporting the view that differences in cultural content (e.g., genre of music) do not necessarily affect brain responses. However, professional musicians demonstrated greater activity in the right superior temporal gyrus in response to both music genres, and in the right midfrontal region for Western music and the left midfrontal region for Chinese music. This latter finding indicates that expertise or training in a given skill, namely, listening to music, enhances activity in brain regions underlying that capacity. Moreover, the rostromedial prefrontal cortex in Western music experts demonstrates sensitivity to Western tonal structure, such that different voxels within this region activate for different tonal keys (Janata et al., 2002). Taken together, these studies illustrate how cortical responses may be shaped by cultural experience.

Culture as a Perceptual Filter

Culture may influence cortical responses not only through the shaping of perceptual experience but also by providing a body of semantic knowledge with which to filter and interpret perceptual experiences. In an interesting attempt to examine whether cultural knowledge influences perceptual experience and its neural correlates, McClure and colleagues (2004) compared neural activity while drinking either Coke or Pepsi. Double-blind behavioral tests indicated that people demonstrate strong preferences for either Coke or Pepsi. Moreover, regression analyses comparing behavioral and neural data revealed that activity in the ventromedial prefrontal cortex (VMPFC) was positively correlated with these behavioral preferences for anonymously delivered Coke and Pepsi. Moreover, when delivery of Coke or

Pepsi was preceded by cultural information (e.g., picture of a Coke or Pepsi can), a broader range of brain regions was recruited, including bilateral hippocampus and DLPFC, relative to when delivery was preceded by a simple light. These results suggest that taste preferences are shaped by at least two kinds of neural response: (1) in the VMPFC, associated primarily with the chemical composition of the drink; and (2) in the bilateral hippocampus and DLPFC, associated with cultural knowledge of the drink. Thus, cultural associations to drinks built up over time through exposure to advertisements, can influence neural activity during gustatory perception and significantly shape gustatory preferences.

FURTHER METHODOLOGICAL CONSIDERATIONS FOR CULTURAL NEUROSCIENCE RESEARCH

The growing number of cultural neuroscience investigations demonstrates the viability of a cultural neuroscience approach. However, just as early cross-cultural behavioral research was hampered by methodological problems, it is important to address methodological issues that hinder the progress of cultural neuroscience research on questions of interest.

Inclusion of Participants from All Cultures

The first issue involves participant sampling and access to necessary equipment. Currently, neuroscience research is conducted on expensive, stationary, and high-maintenance equipment (e.g., fMRI, ERP) available predominantly in rich, industrialized regions within North America, Japan, and Western Europe. Successful application of neuroscience methods to psychology questions requires extensive user training and technical support. This situation severely limits this research to these geographical regions or countries, therefore limiting the groups of participants studied. Evidence of a sampling bias is evident, because over 96% of imaging sites where basic cognitive and affective neuroimaging research is conducted are based in Western Europe or the United States (Raichle, 2003). Thus, one methodological problem that needs to be resolved is how to facilitate neuroscience research for scientists and participants in cultures where the technology and scientific instrumentation necessary to conduct these experiments is absent or difficult

to access. A possible solution is to develop and use neuroscience methods that are transportable to countries where the cultural group of interest resides. The solution to the problem of how to facilitate neuroscience research in regions of the world where the necessary technology does not exist or is difficult to access is likely to require international cooperation and support from governments and private institutions in countries where the necessary scientific technology and infrastructure is already available. Although this is a challenging problem, finding ways to include diverse populations in neuroscience research is crucial to characterize fully mechanisms and structures in the human brain.

Testing within a Culture or between Cultures?

To sidestep this participant sampling problem, most cross-cultural neuroscience investigations to date have been conducted at one scanner site, using recent immigrants or bilingual speakers as participants, rather than multiple scanner sites, so that participants may be tested in their native environment (Gutchess et al., in press; Ketay et al., 2005; Kobayashi & Temple, 2004). Although this strategy has the benefit of eliminating the possibility of introducing noise due to testing environment alone, it may lack some ecological validity because recent immigrants or bilinguals, through acculturation, may identify more with their current culture during testing and adopt strategies optimal for that cultural environment, thereby reducing the probability of finding cultural variation at the neural level. An alternative strategy is to test participants across multiple scanner sites located in each cultural group's native environment (Chiao et al., 2004). This strategy optimizes ecological validity, because the researchers are also likely to belong to the same culture, enhancing the probability that participants' frame of mind while performing the task strictly relates to their own culture. It is possible that this strategy also introduces another potential confound of variance, namely, differences in signal attributable solely to differences in scanner sites. However, previous neuroimaging studies to examine reliability of fMRI and PET results acquired in different testing sites have found that minimal differences in the data were attributable solely to scanner environment, suggesting that comparing imaging results collected from two different scanner sites

is appropriate and potentially a more advantageous strategy for conducting cultural neuroscience research (Casey et al., 1998; Ojemann et al., 1998).

Culturally Appropriate Brain Templates

Another pressing methodological issue involves the creation of culturally appropriate brain templates for spatial normalization of imaging data and brain atlases used for structure–function mapping. For neuroimaging studies, it is necessary to normalize the images of individual brains to a standard spatial template. Some scientists have argued that brain size and shape significantly vary across different racial groups (Park & Gutchess, 2002). Because the spatial normalization templates and brain atlas used currently (e.g., Montreal Neurological Institute [MNI] space and Talairach Daemon) were created by averaging brain images of predominantly white individuals, it is plausible that these templates are inadequate for capturing subtle but significant variation in brain structure that may subsequently affect where differences in brain function are mapped and observed (Evans et al., 1992; Mazziotta, Toga, Evans, Fox, & Lancaster, 1995; Talairach & Tournoux, 1988). Such considerations may be especially important when studying phenomena that reveal themselves in small areas of brain tissue, such as subnuclei within the amygdala.

Selection of Experimental Measures

A third methodological issue concerns the experimental materials used (e.g., stimuli, task, and procedure). As reviewed earlier in this chapter, cultural psychologists faced many problems in developing sound cross-cultural behavioral measures. In adapting these behavioral paradigms to neuroscience research, several considerations emerge (Aguirre & D’Esposito, 1999). First of all, neuroimaging and electrophysiological experiments typically require many trials depending on the type of design. Because some scientists may want to examine cultural variation in neural responses for tasks in which a behavioral difference has already been demonstrated, an event-related design would be most appropriate so that behavioral responses for each trial can be recorded and mapped onto individual physiological events. In particular, event-related fMRI

designs, which involve recording of behavioral and neural responses on a trial-by-trial basis, typically require more power than block or parametric designs; thus it will be important to include a sufficient number of trials per relevant condition (Buckner & Braver, 1999). Furthermore, tasks, instructions and stimulus displays need to be modified, so that they have equivalent meaning across cultures. When designing neuroimaging studies based on prior cross-cultural behavioral work, special consideration may be given to selecting paradigms that yield a large effect because of the typical smaller sample size in neuroimaging studies relative to cultural psychology behavioral studies. Finally, whereas some of the most effective cultural psychology behavioral paradigms involve tasks that require participants to provide responses beyond a button press (e.g., drawing a line or describing an event), behavioral responses in a majority of current neuroimaging environments are restricted to button presses or vocal responses to minimize potential face and body movement, which can create a significant artifact in the neuroimaging data. Although cultural psychology and neuroscience methods bring unique issues to the experimental design table, each of these issues is resolvable, as suggested by recent progress in cultural neuroscience research.

Genotyping Participants

A fourth methodological concern involves integrating cross-cultural genomic data with neuroimaging. Finding an adequate number of participants (e.g., 15–20) who carry the short- and long-allele version of a given functional polymorphism may require genotyping three times the number of desired participants—particularly for polymorphisms that include a rare version. Once preliminary genotyping has identified an adequate number of participants in both cultures, other neural and behavioral testing can be administered. Integrating genotyping with neural and behavioral assays may have profound explanatory power in explaining cultural differences in neural responses and behavior. For example, significant variation may exist in behavior and/or neural activity between cultural groups; however, further inspection may show that these cultural differences are really driven by differences in ratio of short- to long-allele carriers between cultural groups. Although the pragmatic difficulties of

conducting such research are likely to be great, the potential for discovering new ways of explaining cultural variation across all levels of analysis is tremendous.

IMPLICATIONS OF CULTURAL NEUROSCIENCE FOR BASIC AND APPLIED RESEARCH

The ability for a cultural neuroscience framework to provide novel links between sociocultural and biological phenomenon is unprecedented. The development of paradigms and tools with the three fields of cultural psychology, social-cognitive-affective neuroscience, and imaging genomics make this endeavor possible in ways never previously imagined. We do not expect that the study of all psychological and biological phenomena will necessitate a cultural neuroscience approach. Rather, the goal and challenge for cultural neuroscience is to identify the phenomena that *can* be readily mapped within and across levels. It is these phenomena that hold the promise to provide a window into our understanding of the interplay of sociocultural and biological forces.

There are at least two foreseeable benefits of a cultural neuroscience approach for basic and applied research: the merging of natural and social sciences, and the enhancement in the condition; and care of human health across different cultural groups.

Merging the Scientific Study of Culture and Biology

The study of culture and biology has long been stratified within universities and academic subfields, creating a deep conceptual and methodological schism between these different communities of researchers. Snow (1959) once hypothesized that molecular biology could serve as a bridge between the two areas of thought. However, only modest progress has been made so far, because genetic-behavior association studies have only been mildly successful. We hypothesize that cultural neuroscience stands in an even greater position to bridge the culture-biology gap by pulling perspectives and methodologies from every area of psychology (from evolutionary and cognitive to cultural and developmental psychology), as well as from the fields of anthropology, molecular biology, and neuroscience. The tools needed to

investigate the links between multiple levels of analysis are available in ways not previously imaginable, and the results of utilizing these tools to investigate phenomena using a cultural neuroscience approach are likely to enable us to articulate with greater specification our conceptions of culture and its mutually influential relationship with biology. The cultural neuroscience framework aims to reshape the trend to specialize and stay within the confines of one's academic subfield toward a transdisciplinary integration of theoretical knowledge and methodological expertise across the social and natural sciences.

Implications for Population Health

The important interplay of culture and genes in the study of population health has long been appreciated (Shields et al., 2005). This belief stems from the fact that significant differences exist in the frequency with which certain health conditions occur across cultural groups. For example, because of "founder effects," Ashkenazi Jewish people have a greater prevalence of Tay-Sachs disease, and cystic fibrosis is more common among people from Northern Europe (Exner, Dries, Domanski, & Cohen, 2001; Wang & Sue, 2005). Another example is population differences in allelic frequency of the gene *CYP2A6*, which affects the likelihood of nicotine addiction (Shields et al., 2005). Protective forms of the *CYP2A6* are very rare in people who self-identify as European or African (less than 3%), but they are more prevalent in people who self-identify as Japanese or Korean (as great as 24%; Shields et al., 2005). How do differences in genetic frequencies affect brain systems and behavior underlying physical and mental health conditions? How do cultural forces affect the expression and function of these genes, and their effect on brain and behavior?

The answers to these intriguing questions are finally within our empirical grasp. Our hope is that the cultural neuroscience framework may be used effectively to identify and investigate candidate phenomena using the prescribed, multiple levels of analytic approach. By integrating across disciplines and methodologies from cultural to biological levels of analysis, we will meaningfully enhance our chances of understanding of how sociocultural and biological forces interact and shape each other, and finding potential ways to direct this knowledge toward timely issues in population health.

ACKNOWLEDGMENTS

We would like to thank Angela Gutchess, Kristin Bellanca, Nicholas Rule, Jan Leu and participants of the 2002 Harvard Culture, Emotion and the Brain workshop for their helpful comments. This work was supported by a National Science Foundation Graduate Research Fellowship to Joan Y. Chiao and by National Institutes of Health Grant No. R01 MH070833-01A1 to Nalini Ambady.

NOTES

1. alfred.med.yale.edu/alfred/aboutalfred.asp

2. This cultural difference at the level of genes is not in the actual makeup of the 5-HTT functional polymorphism, or in how the gene expresses itself, but in the frequency of carriers of the gene or the ratio of people carrying the short- or long-allele version of the gene in the entire population.

CHAPTER 10

Priming “Culture”

Culture as Situated Cognition

DAPHNA OYSERMAN
SPIKE WING-SING LEE

Culture can be operationalized as a set of structures and institutions, values, traditions, and ways of engaging with the social and nonsocial world that are transmitted across generations in a certain time and place (e.g., Shweder & LeVine, 1984); that is, culture is both temporally continuous and specific. It is located in a time and situated in a geographic and social place. Because of its situated character, culture is neither perfectly transmitted to all members of a cultural group nor is it perfectly uniform across all members of a culture. In other words, though cultures are shared, they are not fully “in the head” of any particular member of a culture (e.g., Mendoza-Denton & Mishel, Chapter 7, this volume). A number of theorists have described the variability in cultural knowledge spread or dissemination within a population (Atran, Medin, & Ross, 2005; Sperber, 2001). These authors all note that because culture is situated, one’s place within a society and the social networks within which one is embedded should influence the aspects of “culture” to which one has access. Both context and change in context (e.g., through immigration) may (Kitayama, Ishii, Imada,

Takemura, & Ramaswamy, 2006) or may not (Atran et al., 2005) carry with it cultural change depending in part on features of the social networks in which one is embedded before and after contextual change.

Situated variability *within* cultural groups is of course not the whole story. The nature and meaning of subtle and not-so-subtle historical and current differences and similarities *between* cultural groups is a main interest of cultural and cross-cultural psychology. Felt difference can be large. Travelogues, comedy routines, diversity training, and business guides all attempt to illuminate (and bridge) differences in how time is understood, what appropriate norms for politeness are, and why other elements of everyday life seem opaque to outside observers coming from different racial/ethnic, religious, or other groups, different societies, nation-states, or regions of the world. Everyday situations, such as how winning or losing in sports is communicated (Markus, Uchida, & Omoregie, 2006); everyday language use such as whether or not personal pronouns can be omitted (E. Kashima & Y. Kashima, 1998); and the everyday assumptions

that make up organizational structures, documents, and mission statements (e.g., Rokeach & Ball-Rokeach, 1989) reflect these differences. Defined in this way, culture is clearly important. As a construct, it captures the breadth and diversity of humanness.

Unfortunately, this very breadth makes it difficult to systematically model “culture” to make predictions about when and how cultures systematically influence cognition, affect, motivation, and behavior. Although understanding a specific culture or a certain group within a culture at a certain time and place may be interesting, parsimonious and predictive rather than detailed and descriptive modeling is the central goal of cultural and cross-cultural psychology. Cultural and cross-cultural psychologists do not simply want to understand the ways that Americans and Japanese differ, or the ways that Germans and Chinese differ. Rather, the essential goal is to understand the ways that culture influences how the mind works and to identify cultural contingencies that moderate general processes of human cognition.

To take on this challenge, cultural psychologists must posit general processes that both differ in their average or likely occurrence across cultures and provide systematic prediction about the what (content) and how (process) of cognition. A number of potentially useful basic organizing constructs (e.g., “tight” vs. “loose” cultures—Triandis, 1995; “masculine” vs. “feminine” cultures—Hofstede, 1980; survival vs. self-expression—Inglehart, 1997; honor-modesty vs. shame—Gregg, 2005; see also Cohen, 2001), and frameworks (e.g., the ecocultural model—Berry, 1976, 1994; Georgas, 1988; 1993) have been proposed to address the basic process question. To date the two constructs that have most captured popular appeal are individualism and collectivism (e.g., Hofstede, 1980, 2001; Kagitçibasi, 1997; Kashima, Kashima, & Aldridge, 2001; Oyserman, Coon, & Kimmelmeier, 2002; Triandis, 1995).

Individualism, as described by Triandis (Chapter 3, this volume), characterizes a cultural syndrome in which the individual is the basic unit of analyses and societal structures are assumed to be of value to the extent that they support individual happiness. Collectivism, on the other hand, describes a cultural syndrome in which the group is the basic unit of analyses and societal structures are assumed

to be of value to the extent that they support preservation and enhancement of group resources. As reviewed by Oyserman, Coon, et al. (2002), plausible consequences of individualism and collectivism for basic concerns of psychology—how we make sense of ourselves and others (self-concept, relationality) and how we think more generally (cognition)—are easily discerned. These are outlined below.

Individualism implies that a basic self-goal is to feel good about oneself as a unique and distinctive person, and to define these unique features in terms of abstract traits. As a cultural syndrome it also implies that relationships are likely to feel chosen and voluntary rather than permanent and fixed; relationships thus construed can be worked on and improved or left when costs and benefits are imbalanced following equity norms. With regard to cognition, judgment, reasoning, and causal inference, individualism as a cultural syndrome implies that focus is generally oriented toward the person rather than the situation or social context, because the decontextualized self is assumed to be a stable, causal nexus (Choi, Nisbett, & Norenzayan, 1999; Miller, 1984; Morris & Peng, 1994; Newman, 1993). Thus, individualism promotes a decontextualized, as opposed to a situation-specific, reasoning style that assumes social information is not bound to social context. Oyserman and colleagues have described this style as a “separate and pull apart” style as opposed to a situation-specific, relational “embed and connect” style (Markus & Oyserman, 1989; Oyserman, Kimmelmeier, & Coon, 2002).

Collectivism implies that a basic self-goal is to attain and maintain group membership, so that the self is defined in terms of both group memberships and the traits and abilities relevant for maintaining these (e.g., loyalty, perseverance). As a cultural syndrome collectivism also implies that important group memberships are ascribed and fixed, viewed as “facts of life” to which people must accommodate; that boundaries between ingroups and outgroups are stable, relatively impermeable, and important; therefore, ingroup exchanges are based on equality or even generosity principles (Morris & Leung, 2000; Sayle, 1998; Triandis, 1995). With regard to cognition, judgment, reasoning, and causal inference, collectivism as a cultural syndrome implies that social context, situational constraints, and social roles figure prominently in person perception and causal reason-

ing (Miller, 1984; Morris & Peng, 1994), and that meaning is contextualized and memory is likely to contain richly embedded detail.

Indeed, a key strength of the individualism–collectivism operationalization of culture is that it sets the stage for specific and testable predictive models. Its parsimony has facilitated use of standard social-psychological priming methods to study effects of making salient features of individualism (or collectivism) on individual-level psychological processes. This narrowed focus of inquiry into culture as operationalized by the individualism and collectivism axes has been helpful in that it has led to specific and novel predictions about how cultural influence works and its impact on basic psychological processes.

For example, E. Kashima and Y. Kashima (1998; Y. Kashima & E. Kashima, 2003) use the individualism and collectivism frame to posit difference by culture group on whether language structure emphasizes or deemphasizes individual actors via pronoun dropping. Dropped pronouns allows the self to be in the background, to introduce one's spouse by saying "wife" rather than "my wife," to describe one's action by saying "going" rather than "I am going." Similarly, Markus and her colleagues (e.g., Markus & Kitayama, 1991; Markus & Oyserman, 1989; Oyserman, 1993) use the individualism and collectivism frame to posit difference by culture group on whether basic self-schemas are separate or connected, resulting in a chronic independent or interdependent way of making sense of the self. Perhaps most intriguingly, the individualism and collectivism frame is being used to posit difference by culture in both content and process of cognition—what and how we think (for earlier reviews, see Oyserman, Coon, et al., 2002; Oyserman, Kimmelmeier, et al., 2002).

In this chapter we provide a brief summary of the mostly correlational evidence suggesting that a focus on individualism and collectivism captures at least some important aspects of culture and cross-cultural difference, highlighting what appear to be systematic differences between Western European and especially Anglo-Saxon-based and other cultures. We then examine gaps in causality that correlational evidence cannot address and propose that to understand the processes underlying how individualism and collectivism influence motivation, cognition, and behavior, more systematic experimental approaches are needed. We high-

light the efficacy of a particular experimental paradigm that involves priming or bringing to mind particular content or cognitive processes. We outline what the priming literature can tell us about the effects of culture (both as operationalized by individualism and collectivism, and as operationalized by other relevant axes, such as high power–low power and equality) on content and process of cognition. We suggest a situated cognition approach to culture and outline what the cultural syndrome priming literature tells us about how culture influences what we think and how we process information about ourselves and the world.

INDIVIDUALISM AND COLLECTIVISM: OPERATIONALIZING, ASSESSING, AND EXAMINING CONSEQUENCES

Operationalization

Individualism is most commonly operationalized as personal independence, and collectivism is most commonly operationalized as obligation and duty to the ingroup, according to Oyserman, Coon, et al. (2002), who examined how individualism and collectivism were assessed in the 20 years after Hofstede (1980) introduced the terms to cross-cultural psychology. Whereas they found 27 distinct scales and noted that no single scale was dominant, they also noted that scale items tended to be modified across studies, so that a subset of items was relatively commonly used. They content-coded scale items, identifying 15 core constructs, seven describing individualism and eight describing collectivism, that together accounted for almost 90% of items across each of the scales.

With regard to collectivism scales, over 85% of scales had at least one item focused on "sense of duty to group," with about 75% having at least one item focused on "relatedness to others." Other identified constructs, in descending order, were "seeking others' advice," "harmony" and "working in groups," "sense of belonging to a group," "contextualized self," and "valuing hierarchy." With regard to individualism scales, almost all scales included at least one item focused on "valuing personal independence." There was less of a consensus on other items, with one-third or fewer of the scales including items focused on "personal achievement," "self-knowledge," "unique-

ness,” “privacy,” “clear communication,” and “competition.”¹

Assessment

As reviewed in this volume by Triandis (Chapter 3) and in a recent thorough review and meta-analytic synthesis (Oyserman, Coon, et al., 2002), there is consistent evidence of the effectiveness of modeling cultural difference in terms of individualism and collectivism. The meta-analytic synthesis compared the United States (European Americans) with other countries, and European Americans with other Americans, on individualism and/or collectivism using all English language studies published between 1980 and 2000 and any unpublished data provided after listserve requests. Cross-national comparisons included 50 studies comparing the United States and at least one other country. Although 64 different countries were represented in the comparisons, almost half of all studies focused on comparisons between East Asian regions and America as befits

the focus on U.S.–Asian comparison in the cultural literature. Within-U.S. comparisons included 35 studies yielding 68 comparisons of European Americans with African Americans, Asian Americans, or Latino Americans. Results provide evidence of average cross-national difference in individualism and collectivism that broadly map onto East and West difference, with some exceptions (Oyserman, Coon, et al., 2002).

With regard to cultural differences in basic values, the meta-analysis shows significant differences in endorsement of individualism values (e.g., personal independence and uniqueness) and collectivism values (e.g., group membership and group processes). Although relying on responses to attitude scales has limitations (see Uskul & Oyserman, 2006, for a review), the overall picture across studies is that on average European Americans are higher in self-rated individualism and lower in self-rated collectivism than Africans, Eastern Europeans, and Asians. This is graphically presented in Figure 10.1. All data points are located in the

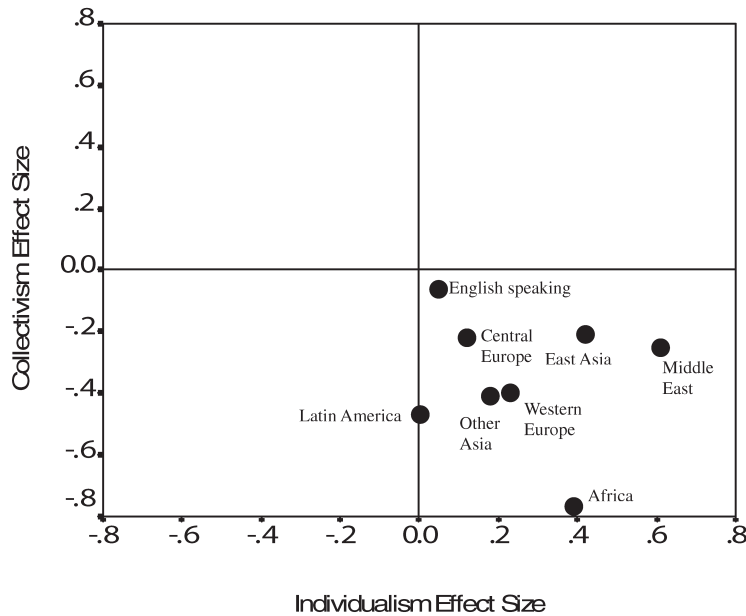

FIGURE 10.1. Are Americans more individualistic and less collectivistic than others? Simultaneous mapping of effects sizes of comparisons between the United States and other regions of the world on individualism and collectivism. Positive effect sizes reflect higher European American individualism and collectivism; negative effect sizes reflect lower European American individualism and collectivism. Adapted from Oyserman, Coon, and Kimmelmeier (2002). Copyright 2002 by the American Psychological Association. Adapted by permission.

lower right quadrant, reflecting higher U.S. individualism and lower U.S. collectivism. Differences are not significant with other English-speaking countries (e.g., Australia, Canada, Great Britain, and New Zealand), suggesting a common cultural core of high individualism and low collectivism. Latin Americans are overall higher in collectivism but not lower in individualism—a cultural syndrome that fits the twin ideas of *machismo* and *simpatico*. Combined effect sizes for comparisons with East Asia were moderate,² as were combined effect sizes for Africa and the Middle East. Taken together, these findings corroborate conventional expectations of cultural theorists.

In addition to this generally confirming picture, Oyserman, Coon, et al. (2002) reported some interesting caveats. First, the meta-analysis suggests that although European American and individuals from other English-speaking countries do not differ in individualism and collectivism, they differ from Western Europeans. European Americans are *lower* in collectivism than Europeans, suggesting a uniquely Anglo-American way of being (high individualism and low collectivism) but challenging the notion of a single "Western" culture.

Second, although the data support the general assertion that European Americans are higher in individualism and lower in collectivism than Asians, effect sizes for Asian regions are similar to those for European regions, with large effects only for U.S.–Africa comparisons. The Asian and European findings challenge the notion of a general "East" versus "West" cultural syndrome and suggest that a more nuanced approach is needed to understand individualism and collectivism within, as well as between, societies. Indeed, Oyserman, Coon, et al. (2002) report large internal heterogeneity within East Asian countries. Consistent with the assumption of high American individualism and low American collectivism, U.S.–China comparisons yield moderate to large effects and do not vary by scale content. But U.S.–Korea and U.S.–Japan comparisons yield small effects for individualism, and collectivism and differences are contingent on scale. No U.S.–Korean difference is found unless collectivism scales include relatedness; if included, Koreans are higher in collectivism. Japanese are lower in collectivism when collectivism scales include

seeking group harmony, defining the self in context, sense of belonging to groups, and acceptance of hierarchy. Japan–U.S. collectivism comparison is in the expected direction (though still small) only when scales include working in a group and exclude seeking harmony.

Third, although two of three within-U.S. comparisons parallel international comparisons, the within-U.S. comparison of African Americans and European Americans shows a stark difference from the U.S.–Africa comparison. European Americans exhibit higher individualism and lower collectivism than Asian Americans, and lower collectivism than Latino Americans (but are indistinguishable on individualism from Latino Americans). However, African Americans exhibit higher individualism and are indistinguishable in collectivism compared to European Americans. These findings (presented graphically in Figure 10.2) challenge the assumption that high individualism and low collectivism is part of a European tradition brought to America and most accessible to European Americans, and suggest that African Americans are in some important ways quintessential Americans.

Moreover, effects for comparisons with Asian Americans and African Americans (though not for comparisons with Latino Americans) are influenced by individualism scale content. Including personal uniqueness items in individualism scales increases the difference between Asian Americans and European American and the difference between African Americans and European Americans. Asian American individualism scores decrease and African American scores increase compared to those of European Americans. Including personal competition items in individualism scales increases the individualism scores of both Asian Americans and African Americans, but not of European Americans. Thus, when individualism scales include personal competition, Asian Americans and European Americans no longer differ in individualism, whereas the difference between African Americans and European Americans increases—with the difference favoring African Americans. Taken together, results suggest first that general assumptions about cross-group differences in individualism and collectivism have some empirical support; second, that future research should not assume that any pair of between-

FIGURE 10.2. Are European Americans higher in individualism and collectivism than African Americans, Asian Americans or Latino Americans? Simultaneous mapping of effects sizes of comparisons between European Americans and other Americans on individualism and collectivism. Positive effect sizes reflect higher European American individualism and collectivism; negative effect sizes reflect lower European American individualism and collectivism. Adapted from Oyserman, Coon, and Kimmelmeier (2002). Copyright 2002 by the American Psychological Association. Adapted by permission.

group difference is due to individualism–collectivism difference; and third, that how individualism and collectivism are operationally defined does matter.

Consequences of Individualism and Collectivism

Taken as a whole, the meta-analytic review suggests that the individualism and collectivism value axes do provide a reasonable organizing structure. If individualism and collectivism differ in meaningful ways cross-culturally, the next question to be answered is the extent that these differences in values matter for how individuals make sense of themselves, how they connect and relate to others, and what and how they think about the world—the plausible consequences of individualism and collectivism described in the opening sections of this chapter. Here, too, we base our conclusions on the review of Oyserman, Coon, et al. (2002), who analyzed the associations of individualism and collectivism with self-concept, relationality, and cognition based on all retrievable English language studies published between 1980 and 2000 (and unpublished data).

Self-Concept

Oyserman, Coon, et al. (2002) reviewed 30 studies that assessed self-esteem, self-concept, or personality, and associated these with individualism and/or collectivism. They found that research typically compared groups within the United States or two countries and assumed differences in chronic cultural syndrome rather than assessed individualism and/or collectivism. If the assumption that cross-group difference is due to difference in individualism and/or collectivism is valid, then an argument can be made that individualism is associated with more optimism or higher self-esteem, whereas collectivism is associated with a more interpersonal and social self-concept. According to this review, effect sizes for self-concept differences are variable. Large effects occur especially when the researcher examined collective or ingroup-focused content and directly assessed individualism and/or collectivism. Because research is either correlational or lacks direct assessment or manipulation of salience of cultural syndrome, research in this domain remains

open to criticism and more critical assessment of the culture → self causal claim.

Relationality

We reviewed 71 studies that assessed close relationships (family, intimate relationships), ingroup–outgroup interactions (social behavior, communication style, conflict resolution style), and work or organizational contexts (working in groups, organizational conflict management). Broadly speaking, these studies suggest that individualism and collectivism as cultural syndromes are associated with differences in relationality and group relations: Individualism is associated with ease of interaction with strangers, preference for direct rather than indirect communication style; collectivism is associated with ingroup preference in relationships and different forms of face saving. Effect sizes are often moderate to large, though highly variable. Effects for conflict management are heterogeneous. Work and organizational research allows for stronger conclusions than close relationship and ingroup–outgroup relations studies, because the former research almost always included both direct assessment of individualism and collectivism, experimental manipulation, and cross-national rather than within-U.S.-only comparison.

Cognition

Whereas research on content of self-concept and relationality supports the notion that individualism and collectivism as cultural syndromes matter in everyday life, potential impact of culture on cognitive process is particularly intriguing, as noted by Norenzayan, Choi, and Peng in Chapter 23, this volume. Oyserman, Coon, et al. (2002) reviewed 39 studies examining cultural and cross-cultural aspects of attribution style, explanations, and persuasion. Americans were consistently more likely to focus on dispositions rather than situations in providing rationales for behavior or explaining causality than were participants from non-Western countries. Where measured, individualism and collectivism appeared to mediate this effect, and where calculable, effect sizes tended to be moderate to large, with separate orthogonal effects for individualism and collectivism.

Whereas the research reviewed by Oyserman, Coon, et al. (2002) focused predominantly on

social cognition, in the past few years, evidence of cross-national differences between the United States, China (Nisbett, 2003) and Japan (Kitayama, Duffy, Kawamura, & Larsen, 2003) in non-social-cognitive processes has emerged as well. This emerging research suggests that Americans are faster and more accurate in recall of abstract and central information, Chinese are more accurate with details and elements of the whole (including the background), and Japanese are more accurate with proportions between elements. Researchers studying cultural and cross-cultural differences in cognition nowadays use experimental methods and diverse participants, providing a strong basis for assertions that individualism and collectivism are associated with differences in cognitive style and attribution processes (for a review, see Norenzayan et al., Chapter 23, this volume).

CULTURE AS SITUATED COGNITION: INTERPRETING THE MEANING OF ASSOCIATIONS BETWEEN CULTURAL SYNDROME AND COGNITIVE CONTENT AND PROCESS

How are these findings to be interpreted? Most provocative is the possibility that culture influences not only the content but also the nature of our thinking. One possible model is that distal differences—in philosophy, religion, language, history—create proximal differences in how we think (Nisbett, 2003; see also Norenzayan et al., Chapter 23, this volume). This perspective, with its focus on distal cultural difference, implies that cultural differences in cognition require socialization in the traditions of one's culture and are hence relatively fixed and difficult to change.

A number of studies suggests otherwise. For example, among immigrants to the United States, Marian and Kaushanskaya (2004) demonstrate that when randomly assigned to use English rather than Russian, participants describe memories that focus on the self significantly more than when these memories are retrieved in Russian. Ross, Xun, and Wilson (2002) demonstrate that when randomly assigned to describe themselves in English rather than Chinese, Chinese students studying in Canada give responses that do not differ significantly from European-heritage Canadians. Among Hong Kong Chinese students filling out questionnaires while Hong Kong was still

under British rule, endorsement of Chinese cultural values *increased* when participants were randomly assigned to fill out the questionnaire in English rather than Chinese (Bond & Yang, 1982; Yang & Bond, 1980). These results suggest that cultural values are complex, can be situationally primed in the moment, and that what comes to mind in the moment is the working subset that is relevant to the task at hand (see also Oyserman, Kimmelmeier, et al., 2002).

Cultures Vary in the Salience of Individualism and Collectivism in Various Situations

What then would be the process by which distal differences influence current meaning making? A possible process model is that various distal differences influence social structures and situations to increase or decrease likelihood of experiencing the self (and the social world) as separate or connected, but that all cultures provide sufficient experience of individualism and collectivism to allow either to be primed when situationally relevant, because all cultures are rooted in evolutionary and natural

selection with the same adaptive needs (see Cohen, 2001; Oyserman, Kimmelmeier, et al., 2002). A society that did not have the potential to invoke group loyalty would not be likely to survive to benefit individual members over time, nor would a society that did not provide spaces for individual choice when group needs were met. Following this reasoning, Figure 10.3 presents a process model linking these distal and proximal features.

The notion that societies in various ways seems at first glance novel. However, quite a large number of social scientists endorse the perspective that individualism and collectivism are not opposing ends of the same dimension but are rather domain-specific, orthogonal constructs differentially elicited by current contextual and social cues (e.g., Bontempo, 1993; Kagitçibasi, 1987; Lehman, Chiu, & Schaller, 2004; Oyserman, 1993; Rhee et al., 1996; Singelis, 1994; Sinha & Tripathi, 1994; Triandis, Bontempo, Villareal, Asai, & Lucca, 1988). As we outline below, thinking about both individualism and collectivism as situationally cued opens the possibility of addressing basic questions about whether and

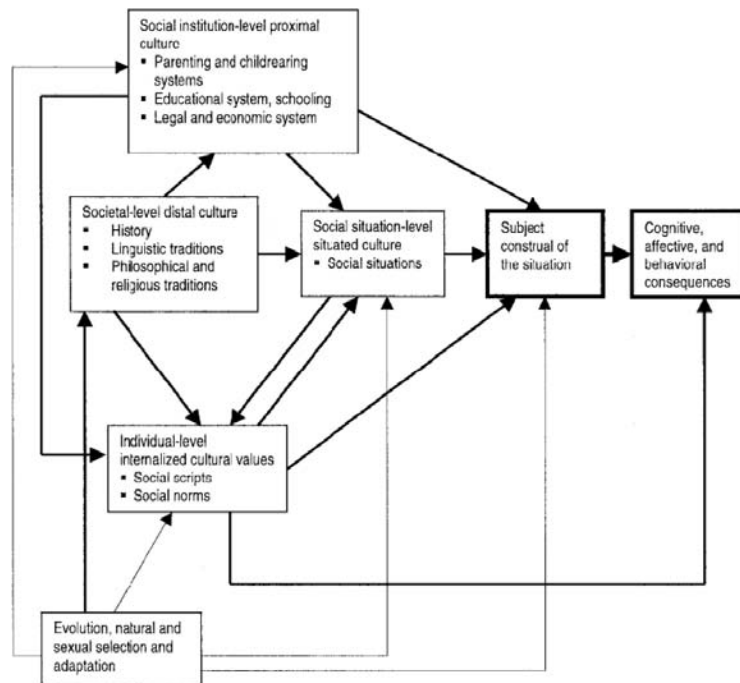

FIGURE 10.3. A socially contextualized model of cultural influences. Adapted from Oyserman, Kimmelmeier, and Coon (2002). Copyright 2002 by the American Psychological Association. Adapted by permission.

how culture might influence content of thoughts (e.g., what comes to mind when one thinks of oneself, which values feel most central, how close one feels to others), and social and nonsocial cognition (e.g., what content and which cognitive procedures comes to mind).

Priming Individualism and Collectivism

Why Use Priming?

Cross-national comparisons and studies using bilingual participants "feel" ecologically valid: They use real differences in terms of where one lives and the language one speaks, and document an association between these differences and how individuals make sense of themselves and their social worlds, and how they think more generally. However, these comparisons make it difficult to answer questions about psychological processing; that is, they are mute as to whether individualism and collectivism are the active ingredients in observed differences, and if so, which aspects of individualism and collectivism make a difference. To answer these process questions, it is necessary to manipulate experimentally the salience of individualism and collectivism as syndromes and to compare results when different facets of these syndromes are brought to mind. Indeed, an emerging experimental technique based in social cognition research involves efforts to prime individualism or collectivism and in this way isolate effects on a dependent measure.

Priming involves making content and/or procedures temporarily accessible. The influence of construct accessibility on social perception is well documented (Higgins & Bargh, 1987). Accessibility can be the temporary result of priming (Srull & Wyer, 1978, 1979) or a more chronic result of routine or habitual activation of a construct in one's everyday environment (Bargh, 1984; Higgins, 1989, 1996). Temporary and chronic accessibility effects are similar (thus, comparable) and independent (thus, additive) in influencing in social judgments (Bargh, Bond, Lombardi, & Tota, 1986; Rudman & Borgida, 1995). Recent priming and chronic activation are both predictive of construct accessibility.

In the laboratory, priming typically involves presenting participants with a series of ostensibly unrelated tasks. When participants are not made aware of a connection between tasks (i.e., of researcher intent to influence them), semantic content and procedural knowledge

cued by the first task "spill over" into subsequent tasks. By studying this spillover effect (e.g., comparing group differences between priming tasks) and comparing spillover effects to cross-national differences, it is possible to test models of cultural influence on content and process of cognition.

Priming as a technique holds promise of creating an experimental analogue of chronic differences between cultural groups by temporarily focusing participants' attention on different culture-relevant content or mind-set. Primes can cue semantic or content knowledge, as well as procedural or mind-set knowledge; culture-relevant values, norms, goals, beliefs, and attitudes can be cued automatically, without participants' awareness. For culture, priming most commonly involves making active ingredients of either individualism or collectivism salient and assessing effect of priming as a between-participant variable.

Of course, priming can only make accessible that which is there. Like all priming methods, the culture-priming tasks can only be effective if semantic content and procedural mind-set knowledge relevant to each construct are available to be primed. Thus, relevant content and procedural knowledge already has to be in memory. One cannot be individualism-primed if one has available in memory only collectivism-relevant semantic and procedural knowledge; similarly one cannot be collectivism-primed if one has available in memory only individualism-relevant semantic and procedural knowledge.

Thus, a basic assumption in priming literature must be that across societies and cultures, individuals are capable of thinking about themselves and the world as both separate and independent, and as connected and interdependent, even if they are typically likely to focus on one or the other. Given universality of both a basic sense of bodily and spatial-symbolic separateness (Burris & Rempel, 2004) and a sense of social connectedness and need to belong (Baumeister & Leary, 1995), this assumption seems warranted. It is not plausible that human minds are structured only to see separation or only connection (see Cohen, 2001; Oyserman, Kimmelmeier, et al., 2002).

CONCEPTUAL PRIMING

The literature on priming has distinguished between conceptual priming and mind-set prim-

ing (Bargh & Chartrand, 2000; Galinsky, Gruenfeld, & Magee, 2003). Conceptual priming, also termed "semantic priming," involves activation of specific mental representations such as traits, values, norms, or goals that then serve as interpretive frames in the processing of subsequent information (Higgins, 1996). Once a concept is primed, concepts associated with it in memory are also activated through spreading activation (Neely, 1977).

Following the auto-motives model (e.g., Bargh, 1990), goal constructs are stored in memory and can be conceptually primed. Once stored, goals for achievement, for power, for remembering, for impression formation, and other pursuits can be primed without explicit, conscious intention formation (Chartrand & Bargh, 1996). For example, Bargh, Raymond, Pryor, and Strack (1995) and Chen, Lee-Chai, and Bargh (2001) exposed participants to words associated with possession of power in the lab and showed priming effects; that is, bringing to mind words associated with power also activated specific, individualized goals associated with power, and these influenced participant perception and behavior. Priming power makes salient sexualized images of women among men already likely to sexually harass (Bargh et al., 1995). Priming power can make salient self-interest or social responsibility goals, depending on individual differences in agentic self-interest versus communal orientation (Chen et al., 2001).

Priming power turned on a semantic network of associated meanings. The result of priming power depended on what participants associated with power. Following this line of reasoning, average between-society or between racial/ethnic group differences attributed to differences in cultural syndrome may be due to differences in the semantic networks primed in everyday situations. Objects and practices continually activate corresponding culturally meaningful concepts and thoughts; that is, cultures may prime different cognitive content by creating differing semantic, associative, and content networks that together influence what we think about ourselves, others, and the world, what feels persuasive, and so on.

MIND-SET PRIMING

Whereas conceptual priming activates a concept or meaning structure, mind-set priming activates procedural knowledge, a way of

thinking (Bargh & Chartrand, 2000). Just as conceptual priming cannot prime novel meaning, but only meaning that has been stored in memory, mind-set priming cannot prime procedural knowledge that does not exist in memory. Mind-set priming involves the nonconscious carryover of a previously stored mental procedure or way of making sense of the world. For example, when primed to think about either whether to engage in a goal (deliberate goal pros and cons) or how to engage in a goal (implement strategies to attain the goal), participants later use this same thinking style in a second, unrelated task (e.g., Gollwitzer, Heckhausen, & Steller, 1990).

Mind-set priming is consistent with a general assumption that processing strategies are situated and tuned to meet current situational requirements (for a review, see Schwarz, 2002, 2006). These processing strategies or procedures can be thought of as part of a procedural tool kit used to structure thinking. When cued, they provide ways of reasoning about the world and have been also termed heuristics or naive theories. For example, experiencing ease might mean that the task was simple or that one is talented. Interpretation depends in part on the naive theory brought to mind to make sense of experience (Schwarz, 2006). Procedural priming cues a procedure, thus allowing it to be set into motion and studied separately from its everyday context.

Social cognition research has suggested a number of likely chronic or easily cued procedures. For example, Schwarz and colleagues (e.g., Schwarz & Bless, 1992; Strack, Schwarz, & Gschneidinger, 1985), in their assimilation-contrast model, describe assimilation as the more chronic cognitive procedure style and contrast as the cue-able alternative cognitive procedure; that is, individuals automatically assimilate and integrate new information with already present information, unless they are cued to use a contrasting procedure. When contrasting is cued, they automatically separate new from already present information. Cues to use a contrasting procedural style include everyday differences triggers such as belonging to a different time, place, or group.

More generally, mood, perceived distance, and perceived power have been studied as procedural triggers. Schwarz and Clore (1996, 2007) describe mood as providing procedural cues: Positive mood cues less effortful, heuristic processing and negative mood cues more

effortful, systematic processing. Trope and Liberman (2003) describe distance and anything that cues distance (including temporal distance) as providing procedural cues (see also Boroditsky, 2000). Distal objects and events are processed abstractly, in terms of core, gist, and superordinate structure; proximal objects and events are processed concretely, in terms of detail, particulars, and subordinate structure. Mood (Gasper & Clore, 2002), power (Smith & Trope, 2006), and self-regulatory focus (Förster & Higgins, 2005) have also been studied as mind-set primes for local versus global processing style. Bad mood, low power, and a caution-oriented prevention self-regulatory focus trigger local processing, whereas good mood, high power, and success-oriented promotion self-regulatory focus trigger global processing.

With regard to cultural and cross-cultural psychology, some of these procedures have been linked to particular gender and cultural groups. Thus, for example, Markus and Oyserman (1989) proposed that women and individuals from non-Western societies are more likely to view themselves as importantly connected. They contrasted women and non-Westerners with men and individuals from Western societies, who are more likely to view themselves as importantly separate from others, and argued that basic cognitive procedures connected with these divergent basic self-schemas cue different cognitive procedures—connect, integrate versus separate, and distinguish. These arguments were refined by Markus and Kitayama (1991) in their follow-up review, in which connected self-schemas were termed interdependent self-construals and separate self-schemas were termed independent self-construals, with the proposal that this difference in self-concept is true of average differences between Eastern and Western ways of self-construal. Cross and Madson (1997) made the same argument for gender (for a different perspective on gender and culture see Kashima et al., 1995).

Following these initial reviews of the literature, empirical work demonstrating the association of “separate” and “connected” self-schemas with preference for “separating” and “connecting” cognitive processes was carried out by Woike (1994). Woike and her colleagues describe connected self-schemas as communion self-concepts and separate self-schemas as agency self-concepts (following Bakan, 1966),

and term the relevant preferred cognitive processes integration and distinction respectively (Woike, 1994; Woike, Lavezzary, Barksy, 2001). They find that the cognitive procedure chronically preferred by those with an agentic self-schema is to distinguish or separate, whereas the cognitive procedure chronically preferred by those with a communal or connected self-schema is to connect and integrate. Following from the separated and connected self-schema models, this difference in basic cognitive procedures has also been corroborated in more explicitly culture-focused research (Hannover & Kühnen, 2004; Kühnen, Hannover, & Schubert, 2001; Kühnen & Oyserman, 2002).

SUMMARY

Priming studies artificially prime or cue certain procedures in a controlled environment. The same outcomes are likely to be cued in everyday situations as well. Both conceptual and mind-set priming processes are likely to occur, and both are likely to be important for researchers seeking to understand the process by which distal differences in societies (their histories, philosophical and religious traditions, and ecological niches) influence “online” differences in the sense individuals make of their social and nonsocial world and how they go about thinking—cognitive content and structure. By focusing attention on likely differences in content and procedures cued in the moment, our goal in this chapter is to provide a causal model of proximal cultural difference rather than a model outlining potential distal cultural difference. We now turn to evidence that culture may influence cognitive content and process either by nonconscious or conscious activation of cognitive content or procedures.

What Is the Evidence That Accessible Cultural Syndromes Influence What and How We Think?

By providing an experimental manipulation, conceptual and mind-set priming techniques hold promise of clarifying at least some of the active ingredients of chronic cross-national differences. However, to demonstrate that priming techniques evoke what is understood to be culture rather than some other semantic and procedural knowledge, the first task is to demonstrate that priming does in fact evoke *culturally relevant* semantic knowledge—values, con-

tent of self-concept, and ways of interacting with others (relationality). That is, priming collectivism (individualism) should make collective (individualistic) values more salient and likely to be endorsed, render relational and group membership (individual traits, unique self-features) content of self-concept more accessible and likely to be recalled, and increase felt closeness to ingroup members. Once this impact of priming on conceptual knowledge has been demonstrated, the impact of priming on culturally relevant procedural knowledge can be examined.

Types of Primes

Because primes are tools or means of evoking semantic and procedural knowledge, causal inference from priming results is strengthened if results are consistent across different types of primes. Consistent effects across differing prime types provide convergent evidence that the latent constructs of individualism and collectivism are being evoked. Similarly, causal inference is strengthened if priming individualism and collectivism works in both Eastern and Western countries, because this will constitute evidence that both Eastern and Western countries socialize for both individualism and collectivism. Before turning to evidence that priming results can be observed using different methods and among members of different cultures, we outline briefly each of the various individualism and collectivism primes used in the field.

Oyserman and Lee (2007) have conducted an extensive review of the culture priming literature. They find that primes are diverse in content, in type of task used, and in their transparency to the participant. This diversity is helpful, if meta-analytic results from priming studies are consistent across these different levels of collectivism primes, this will constitute evidence that the underlying process of collectivism is the same across different levels of groups (relational vs. collective)—an issue unresolved by the cross-cultural, cross-national comparative literature.

With regard to priming individualism, tasks typically focus on the individual self (using “I” as a prime), on the self as different or unique, and on difference and separateness more generally. With regard to priming collectivism, tasks focus not only on connection, using “we” as a prime, but also on similarity or obligation to

family, as well as larger groups, such as teams. That is, collectivism primes focus on what has been termed “relational,” as well as “collective,” identities: friends, family, others with whom one is likely to have a close and personal bond, as well tribal affiliation or membership in larger groups where a close and personal bond with all group members is unlikely (for distinction between relational and collective identities, see Brewer & Gardner, 1996; Roccas & Brewer, 2002).

As detailed below, each of the priming tasks can clearly be viewed as a conceptual prime. Words related to individualism and collectivism are primed and likely to bring to mind relevant values, ways of being a self, ways of engaging with others, and ways of making sense of the world. A question to be explored is whether it can also be shown that these tasks prime procedural knowledge—activating cognitive procedures of separating out and focusing on a main object, the figure versus connecting, integrating, and focusing on the whole. Thus, the question is when words like *separate*, *different*, and *dissociate* or words like *similar*, *connect*, and *together* are used in instructions or in the task itself, do they prime mind-sets rather than simply content knowledge?

Priming Individualism and Relationally Focused Collectivism

While collectivism has mostly been described in terms of focus on group membership, much of the cross-national research has focused on within-group contexts, examining more relational rather than group-level processes. Not surprisingly then, two of the common primes also focused on priming a relational level of “we.” As outlined below, these are the Similarities and Differences with Family and Friends task (SDFF) and the Pronoun Circling task. One or the other of these primes is used in almost half of all culture-priming studies (Oyserman & Lee, 2007).

SIMILARITIES AND DIFFERENCES WITH FAMILY AND FRIENDS TASK (SDFF)

Trafimow, Triandis, and Goto (1991, Study 1) developed this task. To prime individualism or “I” the instructions are as follows: “For the next 2 minutes, you will not need to write anything. Please think of what makes you different from your *family and friends*. What do you expect

yourself to do?" To prime collectivism (in this case a "relational we") the instructions are as follows: "For the next 2 minutes, you will not need to write anything. Please think of what you have in common with your *family and friends*. What do they expect you to do?" (p. 651; italics added). As noted in the italicized text, the focus is on others with whom one has a close relation. The SDFP may be assumed to prime conceptual knowledge: Activating concepts of one's similarities to (differences from) close others should activate relevant values, ways of describing oneself, and engagement with others.

PRONOUN CIRCLING TASK

Brewer and Gardner (1996) developed an initial version of this task that contrasted "we" with "they." This work was refined by Gardner, Gabriel, and Lee (1999), who developed the initial form of the pronoun circling task comparing a focus on "I" (as well as "me" and "my"), with a focus on "we," where "we" refers to friends who go together into the city. Specifically the task is to circle personal singular and plural pronouns in a paragraph. Following the initial work of Brewer and Gardner, a number of different paragraphs have been used. The original paragraph was: *We go to the city often. Our anticipation fills us as we see the skyscrapers come into view. We allow ourselves to explore every corner, never letting an attraction escape us. Our voice fills the air and street. We see all the sights, we window shop, and everywhere we go we see our reflection looking back at us in the glass of a hundred windows. At nightfall we linger, our time in the city almost over. When finally we must leave, we do so knowing that we will soon return. The city belongs to us* (italics added to show relational collective prime). Because the concepts "I" and "we" are primed, the pronoun circling task may be assumed to prime conceptual knowledge: Activating concepts "I" and "we" should activate relevant values, ways of describing oneself, and engagement with others.

Priming Individualism and Collectivism That Is Both Relationally and Collective Group-Focused

Three collectivism primes did focus on the collective level, in conjunction with a more relational level. Two of these primes, scrambled sentence tasks and subliminal priming, are standard in the priming literature. Scrambled

sentences and subliminal prime can in principle use collective or relational words, and indeed, current usage has words such as *team* and *group*, which are likely to be more collective than relational. The third prime has participants imagine themselves in the shoes of a Sumerian warrior, making choices in part due to group (tribe) membership, as well as family concerns; this common prime is similar to the SDFP prime in that instructions simply ask participants to imagine the situation. These primes are also often used, constituting almost 40% of published culture-priming research (Oyserman & Lee, 2007).

SCRAMBLED SENTENCE TASK

The scrambled sentence task (Srull & Wyer, 1979) is one of the standard tools for priming. According to Oyserman and Lee's (2007) review, the following words have been used to prime individualism, the words *I, me, mine, distinct, different, competitive, own, free, unique, dissociate, assertive, unusual, autonomy, alone, apart, autonomous, detached, different, dissimilar, distinct, diverge, independence, individual, isolate, separate, solitude, split, unique, and self-contained* are included. To prime collectivism, the words *we, us, ours, join, similar, alike, share, cooperative, agreeable, help, group, respect, partnership, together, team, support, others, attached, alliance, closeness, cohesive, connection, inseparable, interdependence, intimate, joint, merged, overlap, similar, shared, together, union, and friendships* were used. Given the concepts primed, the scrambled sentence task may be assumed to prime cultural-syndrome-relevant conceptual knowledge.

SUBLIMINAL PRIMING

Subliminal methods are also standard priming techniques. Subliminal priming involves presentation of target words or pictures at a speed too fast (e.g., 35 ms) for conscious processing. Only one published use can be located in the culture priming literature. Oishi, Wyer, and Colcombe (2000, Study 3) included in their priming task the following words: *own, mine, compete, I, me, individual, distinct, and free* (vs. *share, ours, cooperate, us, we, group, same, and team*). Subliminally primed concepts may be assumed to prime cultural-syndrome-relevant conceptual knowledge.

SUMERIAN WARRIOR STORY

Trafimow et al. (1991, Study 2) developed this task. The instructions read, “We would like you to read a couple of paragraphs on the following page. After reading these paragraphs, you will be asked to make a judgment about the main character” (p. 652). The participant is then given a lengthy text to read that either focuses attention on individual-talent or tribe-membership and family considerations as rationale for the choice. Because concepts related to individual choice versus focus on tribe and family are primed, the task may be assumed to prime conceptual knowledge.

*Priming Individualism
and Group-Focused Collectivism*

Two other primes attempted to evoke group focus explicitly in their collectivism primes. Group focus was prime by either instantiating a group in the lab or by having participants imagine that they were part of a team or alone, or by having participants imagine themselves or their family consuming grape juice. While quite different from the other primes, this kind of minimal group fits with classic social identity research (e.g., Tajfel, 1982, 2001; Tajfel & Forgas, 2000; Tajfel & Turner, 2004). It could be argued to be relevant to the cross-national literature examining collectivism via preference for working in groups (see Oyserman, Coon, et al., 2002), as well as to Hofstede’s (1980) workplace-based focus in the initial cross-culture research comparing countries on individualism. To the extent that work group concepts prime relevant cultural syndrome constructs, the tasks may be assumed to prime conceptual knowledge.

GROUP INSTANTIATION AND GROUP IMAGINATION

Three studies used a “group instantiation prime” (Briley & Wyer, 2002, Studies 1–3). Individualism priming involved individual conditions (performing the task individually, being seated at single-person desks separated by partitions). Collectivism priming involved group formation and intergroup competition (being seated at five-person tables, working as a group, giving the group a name, being told that points were rewarded to the group and competing against other groups).

Seven studies used a “group imagination” prime (Aaker & Lee, 2001, Study 2 Pretest, Studies 2–4; Lee, Aaker, & Gardner, 2000, Studies 2–4). Individualism priming involved imagining oneself competing in a singles’ tennis match or consuming grape juice. Collectivism priming involved imagining oneself competing on a tennis team or one’s family consuming grape juice.

Language as Prime

Oyserman and Lee (2006) were able to locate 10 studies (Bond & Yang, 1982; Kimmelmeier & Cheng, 2004; Marian & Kaushanskaya, 2004; Ralston, Cunniff, & Gustafson, 1995; Ross et al., 2002; Tavassoli, 2002; Trafimow, Silverman, Fan, & Law, 1997; Watkins & Gerong, 1999; Watkins & Regmi, 2002; Yang & Bond, 1980) that used language as their priming method. The assumption is that English carries with it knowledge about American or Anglo-Saxon culture and therefore evokes individualism, whereas other non-Western languages carry with them knowledge about a home culture that is assumed to be more collectivist. This prime can only be used with participants who are fluent in both English and another language. Although in principle any two languages can be used, Oyserman and Lee (2007) found studies comparing responses in English to those in Chinese, Cebuano, Nepali, and Russian—languages rooted in cultures assumed higher in collectivism.

Although researchers clearly assume that English is a prime for individualism, and this may be so, it is not entirely clear what exactly is being evoked by use of English. It may be a foreign language (e.g., Kimmelmeier & Cheng, 2004), the language of the colonizer (e.g., Yang & Bond, 1980), or a second home language (e.g., Ross et al., 2002) depending on social-historical backgrounds and social cues, in the experimental situation. Likewise, although researchers clearly assume that use of native language primes some form of collectivism—whether feelings of interdependence, or more general collective focus, it is not entirely clear what is being evoked. Using a non-native language may suggest that one is to communicate with an outsider; therefore, one may need to take the other’s likely frame of reference into account. Thus, the larger context and the context primed by the experiment are both likely to matter. For example, using one’s native

tongue in one's home country with a native-language-speaking researcher may have different effects than if one does so in another country, say, as a student in the United States or Canada. For a Hong Kong Chinese student, the meaning of using English in Hong Kong (e.g., Bond & Yang, 1982) may differ from the meaning of using English in Canada (Ross et al., 2002). These distinctions highlight both the situated nature of language use and its effects on cognition and the need for further work to better understand these situated effects. If language priming shows effects on values, self-concept, and relationality, it can be assumed that language is a conceptual prime. If language priming also shows effects on cognitive processes, then it can be assumed that language is a procedural prime as well.

WHAT DOES THE PRIMING LITERATURE REVEAL?

Priming is a relatively new entry into the cultural and cross-cultural literature. But cultural and cross-cultural psychologists have adopted the primes we introduced earlier to evoke individualism and collectivism, and to examine their effects on a number of dependent measures among various cultural groups. In this section we review the empirical findings of this body of research.

The Nature of the Literature

Oyserman and Lee (2007) conducted a search of the English-language published literature and found 67 studies with 5,818 participants that primed both individualism and collectivism. These priming studies examined effects on values (typically items from Schwartz, 1992; Triandis, 1995; Triandis, McCusker, & Hui, 1990), relationality (e.g., social obligation), self-concept (typically coding from the Twenty Statements Test [TST; Kuhn & McPartland, 1954]), well-being (e.g., life satisfaction), and cognition. Priming studies were conducted in English, German, Dutch, and Chinese. Studies were conducted in four regions and eight countries: North America (the United States and Canada), East Asia (Hong Kong and Singapore), Western Europe (Germany and the Netherlands), and Other Asia (Nepal and the Philippines).

Seven studies presented a cross-national replication of priming effects (Aaker & Lee, 2001,

Study 2 Pretest & Study 2; Briley & Wyer, 2001, Study 4; Gardner et al., 1999, Study 2; Lee et al., 2000, Studies 3–5) and one study presented priming as a replication of cross-national difference (Haberstroh, Oyserman, Schwarz, Kühnen, & Ji, 2002, Study 2). Even though these studies provided information on Hong Kong and China, the bulk of studies ($n = 36$) were conducted in the United States and, whether in the United States or not, most studies were conducted in English ($n = 44$). Studies not conducted in English were conducted in Germany, the Netherlands, and Hong Kong, or used language as a prime. Most studies did not provide explicit information about racial/national heritage of participants. It is unclear whether studies did not provide the information because they did not include racial/ethnic majority participants or whether race/ethnicity was not reported because sample sizes were too small for subgroup analyses. Only about one-third of studies included gender in the design.

Hypothesized Effects

Following the cultural syndrome model described previously, the expected impact of priming on values, self-concept, relationality, and cognition can be outlined as follows: With regard to values compared to when collectivism is primed, when individualism is primed, endorsement of relational or collective values would be lower and endorsement of individualistic values would be higher. With regard to self-concept, compared to when collectivism is primed, when individualism is primed, unique traits and attributes related to self-concept should be more accessible, and social or relational aspects of self-concept should be less accessible. With regard to relationality, compared to when collectivism is primed, when individualism is primed, we expected less accessibility of feelings of social obligation and closeness to ingroup others. With regard to cognition, compared to when collectivism is primed, when individualism is primed, we expected more accessibility of context-independent cognitive processing and less accessibility of context-dependent cognitive processing.

Overall Priming Main Effects

Culture priming had a significant and small-to-moderate effect (mean weighted $d = 0.34$, mean unweighted $d = 0.45$) that did not differ signifi-

cantly when Asian or Asian American compared to European or European American participants were included. Overall, results suggest that priming does influence culture-relevant content (values, self-concept, and relationality) and process (cognition). Effects are relatively robust to prime with some exceptions as noted below. By unpacking the main effect of priming to ask how priming influences each of these culture-relevant constructs and processes, and whether effects are consistent across prime and sample, Oyserman and Lee (2007) provide evidence that at least part of the process by which culture has its effects is via priming of knowledge (semantic priming) and mind-set (procedural priming).

Moderator Analyses

Effect of Prime Type

The majority of studies primed cultural syndrome by using language and six of the seven tasks (with the exception of subliminal priming) described in the prior section. A few studies used various tertiary unclassified primes. The most common priming tasks were Pronoun Circling ($n = 15$), Sumerian Warrior ($n = 12$), SDFP ($n = 10$), and using language as a prime ($n = 10$). Mean weighted effect sizes were moderate for Sumerian Warrior and SDFP primes, and small for Pronoun Circling, scrambled sentence ($n = 7$), group imagination ($n = 8$), and group instantiation ($n = 3$) tasks. Reflecting perhaps the ambiguity of what exactly is being primed, especially small effects (weighted $d = 0.10$) were found for language primes. Estimating effects sizes by whether the collectivism primed was relational, collective, or both, Oyserman and Lee (2007) report moderate effects when collective primes included both relational and collective group levels, but small effects when only the relational or collective level was primed. This increased effect size of the mixed primes may reflect the fact that they were better able to cue cultural-syndrome-relevant content in working memory. Alternatively, these differences may be an artifact of differential use of the primes for different dependent variables. While the most common priming task, the Pronoun Circling task, has been used with a variety of dependent variables (self-concept, cognition, values), other tasks, such as the SDFP, have been used mostly with a single dependent variable.

Effect of Dependent Variable

Significantly different effects of culture syndrome priming were found depending on the culture-relevant construct assessed. Culture syndrome priming had significant but small effects on values (based on $n = 15$ studies) and self-concept (based on $n = 21$ studies), but moderate-to-large effects on relationality (based on $n = 13$ studies) and cognition (based on $n = 28$ studies). To understand the nature of these effects, each culture-relevant construct was assessed separately.

VALUES

Studies examining the effect of priming on values could be divided into those using known individualism and collectivism value scales (as reported earlier, those of Triandis and Schwartz) and those using other value items (e.g., "Chineseness," Bond & Yang, 1982; Ross et al., 2002; Yang & Bond, 1980; emotional connectedness, self-sacrifice, and individuality, Briley & Wyer, 2001, Study 4; equality proverbs, Briley & Wyer, 2002, Study 3; justice values, Kimmelmeier, Wiczorkowska, Erb, & Burstein, 2002, Study 3). Because effect of cultural syndrome priming on responses to known individualism and collectivism value scales is a plausible validity check of the priming manipulation itself, Oyserman and Lee (2006) examined effect size for these studies separately and found effects in the moderate range. This is an important validity check for the priming procedure.

Further analyses reported by Oyserman and Lee (2007) suggest some difference in effect size by prime. Whereas the Sumerian Warrior task, the SDFP, and the scrambled sentence tasks have on average a moderate impact on accessibility of cultural values, the Pronoun Circling task, the group imagination task, and the group instantiation task have only a small effect on accessibility of cultural values. No effect of language priming was found.

SELF-CONCEPT

Among the 21 studies examining the effect of cultural syndrome priming on self-concept, most operationalized it with content coding of variants of the TST (Kuhn & McPartland, 1954). Other studies used items from either Singelis's (1994) or Leung and Kim's (1997)

Self-Conceptual Scales or created their own items. Small effects were found whether researchers content-coded for number of personal traits or number of collective identities generated in the TST. No effect of cultural syndrome priming was found for number of relational identities generated. It is possible that a more complex relationship exists between cultural syndrome priming and self-concept than can be captured by content-coding TST responses; that is, current research is based on categorizing responses as social or personal self-focused. When a social self is cued, however, it seems likely that it will cue how one is that self—for example, thinking of oneself as a daughter or as a Muslim will cue the relevant traits associated with this identity (e.g., willful or obedient). If each word is coded separately, then the latter descriptors will be coded as private selves, yet this may not be how they are intended (for further discussion of this issue see, e.g., Oyserman, 2007).

It is also possible that effects are dependent on prime type. When language was used as a prime with English as the individualism prime, and Chinese (Ross et al., 2002), Cebuano (Watkins & Gerong, 1999), or Nepali (Watkins & Regmi, 2002) as the collectivism primes, participants referred more to others in Chinese than in English, and described more relational but fewer collective selves in Cebuano and Nepali than in English. However, they also used more trait self-descriptors in Cebuano. Further analyses reported by Oyserman and Lee (2007) suggest that the Sumerian Warrior, the Pronoun Circling, the group imagination, and the language priming tasks all have on average a small effect on accessible content of self-concept, whereas the SDFF task has on average a moderate effect. The SDFF task involves bringing to mind similarities to (or differences from) family and friends, suggesting that the effect of priming on self-concept content may be particularly clear when the prime brings to mind semantic content that is very close to the task at hand.

RELATIONALITY

Average effects of priming cultural syndrome on relationality are moderate. Some studies show effects on reported social obligation (e.g., Gardner, Gabriel, & Dean, 2004). Other studies show effects on behavioral measures of psychological closeness (Holland, Roeder, van

Baaren, Brandt, & Hannover, 2004, Study 2); that is, relative to when individualism was primed, when collectivism was primed, participants sat closer to a confederate.

Size of effect appears to be dependent on the type of prime used (Oyserman & Lee, 2007). Further analyses reported by Oyserman and Lee suggest that language priming has a small effect on accessible knowledge about relationality; the Sumerian Warrior task and the Pronoun Circling task have, on average, a moderate effect, and the SDFF and the scrambled sentence tasks have on average a large effect. Whereas the SDFF explicitly focuses on relationships, scramble sentence tasks do not, so the larger effect in the latter two prime conditions is unlikely to be solely due to bringing to mind family and friends.

COGNITION

Taken together, studies priming cultural syndrome and then assessing accessibility of individualism and collectivism values, relationality, and relevant self-concept content provide assurance that priming cultural syndrome using the kinds of primes described previously does seem to activate relevant constructs and make accessible the values, and ways of thinking about oneself and relating to others described in the cross-cultural literature. These results suggest that at least in part, culture's impact is via priming of semantic knowledge and networks.

Social cognition studies support this claim, showing effects of priming on conceptual knowledge. For example, Haberstroh et al. (2002, Study 1) find that semantic priming of cultural syndrome shifts sensitivity to conversational norms, making collectivism-primed German participants as sensitive as nonprimed Chinese participants. Taken as a whole, the results of cultural-syndrome-priming studies not only provide a "live" process model but also highlight that cultural impact is indeed situated in the immediate context. Contexts are cultural because they evoke certain values, ways of being a self, ways of engaging others, relevant attitudes, and sensitivities to others.

Although a process model that focuses on conceptual priming effects is interesting, as we noted at the outset of this chapter, cultural psychologists have argued for an even deeper impact of culture. Cultural psychologists have argued that culture influences not only what we

think but also how we think. The studies priming cultural syndrome, then assessing accessibility of relevant cognitive procedural knowledge provide insight into this latter claim. Thus, for example, Stapel and Koomen (2001, Study 1) primed cultural syndrome, then presented participants with social comparison information. They found that participants were more likely to contrast their self-description with the other after individualism priming and more likely to assimilate information about the other into their self-description after collectivism priming. These effects suggest effects of priming on mind-set, in this case, use of a contrast or exclusion-focused cognitive mind-set procedure rather than an assimilation or inclusion-focused cognitive mind-set procedure.

In the cognitive domain across studies, effect size was moderate whether the cognitive construct assessed was an attitude, judgment, or social cognition (and the prime activated conceptual knowledge), or a nonsocial cognitive process was assessed (and the prime activated procedural knowledge). In an example of procedural priming, Kühnen and Oyserman (2002) showed that priming cultural syndrome influenced speed with which respondents recognized letters in an embedded letters task (Study 1) and accuracy of recall of figures embedded in context (Study 2). More recently in our lab we have demonstrated that priming cultural syndrome influences Stroop color-naming latency effects. Because the Stroop task requires participants to separate and pull apart features of the stimuli, both Americans and Koreans showed effects such that relative to collectivism priming, individualism priming speeds latency of accurate Stroop color response on difficult trials (those in which color and word are incongruent; Cha, 2006; Oyserman, Sorensen, & Reber, 2006).

The procedural knowledge that appears to be primed by the cultural syndrome tasks focuses on separate versus connected reasoning. This distinction is similar to the one made by Nisbett and his colleagues (see Norenzayan, Choi, & Peng, Chapter 23, this volume) but does not require that the cultural syndrome itself be set by distal cultural features such as Eastern versus Western cultural and philosophic and religious traditions. Further analyses reported by Oyserman and Lee (2007) suggest that effects of priming cultural syndrome on cognition are relatively robust to the specific

prime used. The Sumerian Warrior task, the Pronoun Circling task, the SDFE, the scrambled sentence task, group imagination, and language as prime all have on average a moderate effect on both cognition content and process (though effects for the group instantiation task are small³). Taken as a whole, the cultural syndrome priming studies suggest that there is a procedure relevant to the individualism syndrome and a procedure relevant to the collectivism syndrome.

Comparison of Priming Cultural Syndrome with a Control Comparison Condition

Although most studies did not provide a control condition, those that did use a control comparison show a small effect size for both the comparison between individualism prime and control and the comparison between collectivism prime and control. In these control comparison studies, effects for individualism priming did not depend on which dependent variables were assessed, whereas for collectivism priming, effects were moderate for relationality and cognition, and extremely small for self-concept and values. Relative to control conditions, on average, individualism priming produced greater shift than collectivism priming, with two caveats. First, studies using the scrambled sentence task produced equal shift from comparison whether individualism or collectivism was primed. Second, when collectivism priming included both relational and group-level collective focus, a larger shift from comparison for collectivism priming than for individualism priming was observed. Taken as a whole, no single priming task can be considered the gold standard for future work. However, the mixed-level collectivism primes and the scrambled sentence primes seem to provide a mix of ecological validity (taking into account multiple levels) and maximal control (content of sentences can be tailored to enhance results).

SUMMARY AND CONCLUSIONS

Cross-cultural comparisons suggest that culture matters, influencing how the self is defined, how relationships with others are imagined, what is of value and worth, and how the mind works. Cross-national comparisons can be high in ecological validity: They demon-

strate real differences between real groups. A meta-analytic review suggests that cross-national variability in culture is patterned, that assumed value differences can be assessed through survey response. However, these studies are limited. Reliance on survey response leaves open questions about interpretability of comparisons, and studies that lack experimental manipulation cannot illuminate the process by which culture matters, leaving as a black box the mechanism through which culture influences individuals. To address these problems, social cognition research provides semantic and procedural priming as tools to assess the impact of some key aspects of cultural syndromes on content and process of thinking.

To answer these process questions, it is necessary to experimentally manipulate the salience of individualism and collectivism as syndromes and to compare results when different facets of these syndromes are brought to mind. A recent comprehensive review of the cultural-syndrome-priming literature supports the cross-cultural psychological contention that culture matters; that is, priming some culture-relevant content shows a clear impact on accessible cultural knowledge, resulting in shifting values, altered descriptions of content of self-concept, and differences in understanding about one's social obligations and relations with others. These findings suggest that culture is a conceptual prime, activating relevant knowledge. Perhaps most importantly and fundamentally, priming influences situated cognitive process in culturally meaningful ways; that is, priming individualism and collectivism cultural syndromes made accessible different procedural knowledge. The mind-set of individualism is to pull apart and separate, to contrast figure from ground, self from other. The mind-set of collectivism is to connect and integrate, to assimilate figure with ground, self with other. These findings suggest that culture is also a procedural prime, activating relevant naïve theories as to how to make meaning.

Cultural-syndrome-priming literature does not simply support prior suppositions about the influence of culture. It also provides new information suggesting that individualism and collectivism do influence how we think, the cognitive procedures evoked. Moreover, far from being immutable, cultural differences are malleable in the moment. Because cultural syndrome priming can be understood as setting up a situation that cues or makes subjectively sa-

lient isolated active ingredients of culture, the evidence that cultural syndrome priming is effective suggests that such malleability is also plausible in everyday life. Subtle priming evoked subjective construals that afford and elicit culturally meaningful and relevant thoughts, feelings, and behaviors. Thus, although they feel natural, real, and immutable, cultural meanings and cultural differences are likely fluid. Like any other reasoning, culturally situated reasoning is action-based; the situation cues what is relevant to making meaning and taking action in the moment. The finding that cultural syndrome priming influences both content and process is particularly important, because procedural knowledge or naïve theories about how to process information and make meaning of meta-cognitive experience matter for the sense we make of not only ourselves and others, motivation, goal pursuit, and goal persistence but also for intergroup dialogue.

Clearly there is much to be done. Priming research does not yet include regions of the world such as Latin America, Africa, and the Middle East. To understand more about the underlying process, to make predictions with regard to differences in real groups other than college students, it will be necessary to conduct priming research off college campuses. Good cultural syndrome primes should provide the ability to test effects within and across countries, and to test effects with non-college-student participants. Use of varied primes is recommended because no prime alone should be assumed to embody fully the latent construct of "culture" or even its active ingredients.

Moreover, cultural-syndrome-priming research to date has focused on the procedural knowledge likely to be linked with individualism and collectivism, and has not yet begun to examine the procedural knowledge associated with other cultural axes. Culture itself is not just individualism and collectivism, and the priming literature should not be confined to this particular domain. A likely future focus is Hofstede's (1980) power distance construct.

Thus, Shavitt et al. (2006) have provided evidence that, taking hierarchy into account (what they have termed "horizontal" and "vertical" individualism and collectivism) adds to predictions based solely on individualism and collectivism. Disentangling power and individualism-collectivism may be an important step toward utilizing priming techniques

to study this syndrome. For example, Oyserman (2006) has proposed that the relevant cultural axis may focus on responses to high power, low power, and equality, separate from individualism and collectivism. Fiske (1991) and others have suggested that priming to have power is likely to cue global processing, and priming not have power is likely to cue local processing.

Culture-based power researchers will also want to know what happens when equality is cued. Whether equality cues high-power or low-power cognitive procedures is likely to depend on whether equality is synonymous with lack of power within a culture. Much like individualism and collectivism, cultural-syndrome-priming research can begin to provide information about both the content and the procedures that these cultural syndromes bring to mind. Future high- and low-power cultural syndrome researchers will need to examine impact on both content and procedures, as well as to ask whether power, once primed, has the same effect on mind-set or procedural knowledge cross-culturally and whether equality, once primed, carries with it high or low power-linked procedures.

Articulating effects of power separate from as well as in conjunction with individualism and collectivism may increase clarity of prediction. Priming individualism and collectivism could have very different effects on values in contexts that are simultaneously high or low in power. For example, using Triandis's articulation of horizontal and vertical individualism and collectivism, it is possible that in a vertical, individualist culture, priming individualism should lead to endorsement of inequality or competition, whereas in a horizontal, individualist culture, priming individualism should lead to endorsement of equality.

Finally, future research is also needed to untangle language and other features of priming. As noted in this volume (e.g., Chiu, Leung, & Kwan, Chapter 27; Norenzayan et al., Chapter 23; Wang & Ross, Chapter 26; all this volume), language itself is related to culture, memory, and cognition. Although studies using language are limited to participants who are bi- or multilingual, potential effects of language can be operationalized and studied with other primes, thus disentangling language from other culture-relevant factors. To date average effects for language prime studies are very small. This may be due to the necessity of using populations that

know two or more languages well. These bilingual or multilingual people are likely also to be to some extent bicultural or multicultural. Regardless of the type of prime used, populations that chronically move back and forth between cultural frames may be different from other populations.

Indeed, one form of priming research has focused explicitly on bicultural or multicultural individuals (Hong, Morris, Chiu, & Benet-Martínez, 2000). This work uses icons (e.g., the Great Wall of China, the Statue of Liberty) to cue one cultural syndrome or another. Because of this focus on individuals with detailed knowledge of multiple cultures, this work is somewhat different in focus from the research we have reviewed. Like the language priming requirement that participants know two or more languages well, this form of priming requires that participants know more than one culture well. Rather than assuming that all societies include both individualism and collectivism, this body of work assumes that some individuals experience both individualism and collectivism due to immigration or globalization of American cultural influence. Because of this focus, icon priming research can be seen as rooted in research focused on immigration, acculturation, and acculturative stress. However, in principle, icon-based priming should be able to show effects for both semantic and procedural knowledge.

Current research evidence does not include replication of effects with biculturals using language and icon priming, and with others using other priming tasks. Therefore, we cannot yet tell whether effects are the same or different between these populations, and if there are differences whether these are in quantity (i.e., effect size), quality (e.g., whether both content and procedural knowledge can be primed), or in both quantity and quality of effects. We speculate that effects will not differ in quality but may differ in quantity across groups more or less exposed to cultural shifts. Following our model of culture as situated cognition, it is likely that neither language alone nor biculturalism alone explains differences across postmodern societies. Rather, effects are due to situated meaning. Language and icons matter to the extent that they carry meaning in context. Meanings in situation matter, because culture from our perspective is a form of situated cognition; it provides cues as to who one is, what is meaningful, and how to process information about the world.

NOTES

1. Whereas the bulk of research on culture focuses on these two loosely defined cultural syndromes, a number of related constructs are not fully integrated into this body of work. Oyserman, Coon, et al. (2002) note that authors disagree as to whether familialism (relatedness to family, seeking harmony with family members, supporting and seeking advice from family) is *separate* from collectivism (Gaines et al., 1997), the *essential core* of collectivism (Lay et al., 1998), or an important *element* of collectivism, distinct from a nonkin-focused type of collectivism (Rhee, Uleman, & Lee, 1996). Similarly, the place of hierarchy and competition within an individualism and collectivism framework is not fully articulated. Hofstede (1980) originally proposed individualism and power, or as he termed it, "power distance," as separate cultural factors, a view paralleled in Fiske's (1991) taxonomy of basic social relationships, and more recently advocated by Triandis and his colleagues, who proposed including hierarchical or egalitarian aspects of social relationships in analyses of individualism-collectivism (cf. Singelis, Triandis, Bhawuk, & Gelfand, 1995; Triandis & Gelfand, 1998). By including a horizontal-vertical dimension to discussion of cultural differences, different dimensions of individualism and collectivism can be distinguished depending on whether they presume equal or different status between individuals, namely, "horizontal individualism," "horizontal collectivism," "vertical individualism," and "vertical collectivism." According to this framework, cultures high in horizontal individualism tend to be egalitarian, with individuals being independent and of comparable power and status. Countries identified as having this pattern are the Scandinavian countries (Singelis et al., 1995; Shavitt, Lalwani, Zhang, & Torelli, 2006; Triandis & Gelfand, 1998). Cultures high in horizontal collectivism tend to be egalitarian, with individuals committed to the good of the group; only Israeli kibbutzim are identified with this pattern (Shavitt et al., 2006). Most high individualism cultures tend to champion competition between individuals, resulting in acceptable inequality between individuals; most high collectivism cultures also include both clear hierarchies and acceptance of differential outcomes given one's place in the hierarchy. Thus, although equality is thus possible, most cultures are "vertical" to some degree (Shavitt et al., 2006). Triandis's work does raise the question of whether cultures differ in how high and low power influence the sense individual members make of themselves and their world—what and how they think. This is explored further in a later section.

2. Effect sizes are reported following the recommendations of J. Cohen (1992) in interpreting the meaning

of the observed effect sizes: Effect sizes of less than $d = 0.2$ are described as "small"; those of $d = 0.5$ – 0.7 are described as "moderate"; and those above $d = 0.8$, as "large."

3. Small effects were also found for studies that pursued a more complex interaction effect. Lee, Aaker, and Gardner (2000, Studies 2–4, Aaker & Lee, 2001, Studies 1–4), Briley and Wyer (2002, Study 3), and Mandel (2003, Study 1) all examined the hypothesis that priming individualism and collectivism is potentiated when matched with primed or chronic self-regulatory focus (individualism matched with promotion focus, collectivism matched with prevention focus). Across these studies, a small effect was found for match.

PART III

**IDENTITY AND
SOCIAL RELATIONS**

CHAPTER 11

Social Relationships in Our Species and Cultures

ALAN P. FISKE
SUSAN T. FISKE

Social relationships are the primary channel through which cultures are transmitted, and conversely, culture informs social relationships. This occurs because culture is what organisms acquire by interacting in a community or social network; that is, culture includes those aspects of organisms' capacities, motives, ideas, biology, practices, institutions, artifacts, and landscapes that result from engaging in social relationships. Humans have exceptional specializations for learning from others, including a sophisticated capacity for imitating purposeful action. Humans also have proclivities to modify their innate social-relational dispositions in accord with the precedents, principles, and prototypes provided by the communities in which they participate. Thus, culture is transmitted through culturally informed social relationships.

But how does this work? How does the human psyche enable people to bootstrap their social relations, using universal mechanisms to develop culturally particular forms of sociality? To answer this fundamental question for cultural psychology, we need to know what aspects of human social relations are endogenous

(intrinsic to humans), and how these universal aspects give rise to cultural variation. At the same time, we need to know how people recognize and deploy the actions that create and modulate social relationships. Finally, we need both to identify the core motives that drive sociality and to determine how culture shapes their intensity and orientation. These are the questions we explore in this chapter.

This chapter first presents some perspectives on culture and social relationships. The first perspective considers five *core social motives* that motivate people to relate to others in the first place. Then we describe 15 highly salient human relationships, the *roles* most often culturally elaborated, socially institutionalized, cognitively schematized, and emotionally motivated. Cultural and social psychologists have generally ignored most relationships that are phenomenologically salient around the world. A third perspective analyzes four *relational models* that people use to coordinate with each other; these are the elementary building blocks that people implement in culturally distinctive ways and combine to construct complex social systems. The fourth perspective focuses on how

people perceive outsiders and strangers in a two-dimensional *framework of warmth and competence*, based on intent and status. Finally, we tie together the third and fourth perspectives for a more general take on *how people respond to each other*. All these perspectives explain ways that universal social-psychological adaptations give rise to culturally particular social-psychological processes.

CORE SOCIAL MOTIVES

Over the last century, psychologists have repeatedly identified a limited set of core social motives that underlie human behavior (S. Fiske, 2004; Stevens & Fiske, 1995). An essential foundation of the human adaptive niche is other people—the social groups, networks, and relationships in which humans participate (Caporael, 1997; A. Fiske, 2000; S. Fiske, 2004). Most important, people seek *social belonging* with their own kind, the most basic social motive of all (S. Fiske, 2004; Baumeister & Leary, 1995). Belonging enables people to survive and thrive (e.g., Berkman, Glass, Brissette, & Seeman, 2000; House, Landis, & Umberson, 1988; Stansfield, Bosma, Hemingway, & Marmot, 1998). People's core social motive to belong with others ensures their attempts to gain acceptance and avoid rejection (S. Fiske, 2004). From these attempts follow the remaining core social motives: to maintain socially shared *understanding*, a sense of *control* over outcomes, a special sympathy for the *self*, and *trust* in certain ingroup others. The core social motives provide a potentially universal perspective on human sociality, as we shall see.

Belonging

The importance of belonging is a cultural constant. To illustrate the complementarity of our species' evolved proclivities and their cultural variations, consider this core social motive of belonging. Although people are attracted to others everywhere and form relationships everywhere, the mechanisms differ slightly. For example, similarity predicts attraction, at least across wealthy, educated cultural samples that have been studied (Bond & Smith, 1996; Rai & Rathore, 1988), and this makes adaptational sense. Similarity correlates with ingroup membership, suggesting more trust and control than

outgroup members probably afford, especially given that their goals may differ from those of the ingroup (S. Fiske & Ruscher, 1993). Similarity also functions to affirm mutual group membership by indicating that the people involved represent variations on the group's shared prototype or image of itself (e.g., Abrams, Marques, Bown, & Dougill, 2002; Hogg, 2001). Familiarity, often correlated with similarity, also encourages friendship (a type of ingroup formation) in both American and Japanese samples, for example (Heine & Renshaw, 2002).

However, cultures may vary in the extent to which people value similarity in relationships, with Americans valuing similarity more (Heine & Renshaw, 2002). Of course, Americans might define "similarity" as having a single, shared attribute or interest, whereas Japanese might require more shared attributes to feel similar.

Relatedly, cultures may combine universal principles with culture-specific enactments in other domains that encourage relationship. On the one hand, cultures tend to agree about what is physically attractive (Berry, 2000). For both men and women, young, symmetrical, and prototypical features are good. Some features obviously depend on gender; for example, in women (Cunningham, 1986; Cunningham, Roberts, Barbee, Druen, & Wu, 1995), child-like features (large eyes spaced far apart, small nose, small chin), some mature features that might also indicate being slender (narrow face, prominent cheekbones), expressive features (high eyebrows, large smile), and sexual cues (larger lower lip as in a sexual pout, well-groomed, full hair) are favored. What is attractive in men is less often studied, but high cheekbones and rugged jaws appear to be favored (Berry, 2000).

On the other hand, although physical attractiveness predicts interpersonal attraction in many cultures, cultures vary in what they infer from beauty. Western samples report that beautiful people are socially warm and skilled (Feingold, 1992). Several East Asian samples appear to link attractiveness to a cultural ideal distinct from Western ones (Chen, Shaffer, & Wu, 1997; Dion, Pak, & Dion, 1990; Shaffer, Crepaz, & Sun, 2000; Wheeler & Kim, 1997). Chinese immigrants to Canada, those most involved in their Chinese community, do not display the American attractiveness stereotype (Dion et al., 1990). A physical attractiveness

stereotype, however, does emerge in some Asian cultures (Korea and Taiwan), but the content differs. Unlike people in the United States, attractive people in Korea are not presumed to be more powerful but are instead presumed to show more concern for others and more integrity. American and Korean views of social potency apparently differ (Wheeler & Kim, 1997). For Taiwanese participants, cultural context also mattered: Taiwanese who endorsed Western values showed the stereotype most on individualist traits (Shaffer et al., 2000), whereas those who most accepted Chinese traditions showed the stereotype on the most extreme (positive and negative) traits but not more moderate ones, presumably less important (Chen et al., 1997). In each case, although certain aspects appear universal (the importance of belonging, responding to similarity, and attractiveness), the culture shapes the specific manifestations.

Belonging Securely versus Widely

Belonging, the most central core motive, is posited to be universal, but it is enacted differently depending on culture. Several theories contrast Eastern and Western views, with relevance for belonging. Cultural self theory (Markus & Kitayama, 1991) contrasts Japanese interdependent selves, focused on relational motives to maintain harmony, with American independent selves, focused on self-enhancing motives to keep autonomy. Basic trust theory (Yamagishi & Yamagishi, 1994) contrasts Japanese caution with American trust, respectively requiring a long confirmation and preference for well-known associates versus a short confirmation and openness to strangers.

Different enactments of belonging motives fit several cultural observations. Individualists have more relationships, but collectivists appear to have closer, more sensitive, and fewer relationships, with more rules (Verkuyten & Masson, 1996). Americans feel a moral duty to help a relative, depending on how much one likes the relative, whereas Indians find it is a moral duty to help a relative regardless of individual liking (Miller & Bersoff, 1998). East Asian close relationships are more often involuntary, stable, and good enough (Ho, 1998). People are often closer to their families of birth in East Asia than in Western settings (Takahashi, Ohara, Antonucci, & Akiyama, 2002). For example, spousal relationships are

secondary to father–son relationships in Confucian hierarchies. Cultures do differ dramatically in their expectations about marriage (Bond & Smith, 1996; Smith & Bond, 1994). One broad-brush contrast would be marriages arranged to reinforce social networks versus individual romantic choice. Attachment processes may respectively emphasize symbiotic harmony or generative tension between individuals and relationships (Rothbaum, Weisz, Pott, Miyake, & Morelli, 2000). But in many settings, people perceive their own relationships as better than other people's (Endo, Heine, & Lehman, 2000).

Broadly, though, the theme of wide versus secure belonging captures some cultural variations (S. Fiske & Yamamoto, 2005). These cultural variations in belonging underlie variations in the other core social motives that operate in the service of this fundamental, universal motive for belonging as noted earlier: shared understanding, effective control, self enhancement, and trust.

Understanding

To belong, people seek a *socially shared understanding*; this proves to be a core social motive (Augoustinos & Innes, 1990; S. Fiske, 2002a, 2004; Hardin & Higgins, 1996). If you are the only one who thinks that every glacial granite boulder can potentially crush you, you will not travel easy in Vermont, and locals will think you are nuts; conversely, if you do not believe in witches and sorcery, you will not understand events in Burkina Faso, and locals will think you are nuts. People are demonstrably motivated to develop a socially shared understanding of each other and their environment. A shared information framework allows people to function in groups and in any kind of relationship. It informs their assessment of their own rejection and acceptance. This understanding is likely to operate along particular dimensions that facilitate belonging, and these dimensions are, we suggest, pancultural.

Understanding Relationships versus Persons

Although socially shared understanding appears universal, people's strategies for understanding also show some cultural variation, consistent with emphasis on autonomy and unvarnished honesty, or emphasis on interdependence and social harmony. For example, in An-

glo American culture, people focus on understanding individuals, but in more interdependent cultures, people may well focus more on understanding networks of relationships among people.

Controlling as a Group or Individual

People are highly motivated to know the contingencies between their own actions and outcomes (S. Fiske, 2002a, 2004). Feelings of control reflect feeling effective in one's environment. Attributional processes operate in the service of perceived intentional control, another core social motive (S. Fiske, 2004; Pittman, 1998). Feeling efficacious promotes both individual health and group life, so people try to restore lost control, but cultures and individuals vary on this motive. Exactly how people imagine another's intentions depends on cultural factors (A. Fiske, Kitayama, Markus, & Nisbett, 1998).

Previous research on interdependence shows that American students do attend to persons who control their outcomes, and this effect correlates with measures reflecting a basic motive for a sense of personal control (Dépret & Fiske, 1999; Erber & Fiske, 1984; Neuberg & Fiske, 1987; Ruscher & Fiske, 1990; Stevens & Fiske, 2000). Americans, at least, search for information that will restore a sense of personal prediction and control when their outcomes depend on another person. Similarly, when their sense of control is threatened generally, they search for information about others in their environment (Pittman & Pittman, 1980).

Cultural differences in control (A. Fiske et al., 1998) reflect varying emphases on social harmony: the extent to which the individual cedes control to ingroup others, seeking to create and maintain collective compatibility. For example, a scale of harmony control (Morling & Fiske, 1999) includes items such as feeling secure in accepting the care of friends, getting one's own needs met by meeting the needs of others, and going along with intangible forces larger than the self. As one cultural contrast, for example, Texan Latinos score higher than Texan Anglos. As another example, independent Americans achieve control by influencing the world, whereas interdependent Japanese achieve control by mature adjustment and compromise to circumstances and relationships. American women with normal pregnancies coped best by individual acceptance,

whereas Japanese women coped best by social assurance (Morling, Kitayama, & Miyamoto, 2003). In general, Americans specialize in primary control, whereas Japanese and other East Asians may specialize more in cooperation-based secondary control (Morling & Evered, 2006).

Self-Enhancement

Maintaining a *special status for the self* appears to be yet another core social motive (S. Fiske, 2004). This special status (whether inflated self-esteem, self-improvement, or self-sympathy) depends on culture but seems to engage self-protection, self-improvement, and self-maintenance.

Enhancing Relationship versus Self

The self plays a special role in people's lives. In a wide-ranging literature review, many Western samples tend to enhance the self relative to other people, or relative to other people's view of them (Kwan, John, Kenny, Bond, & Robins, 2004). But the Japanese, for instance, tend to be more modest and view the self more in the context of group memberships (Markus & Kitayama, 1991). Some have posited that East Asians view the self with a special sympathy, despite its admitted flaws (Heine, Lehman, Markus, & Kitayama, 1999). This self may be improved, although the task is difficult and success is not guaranteed. Sympathy in relationships balances against self-criticism, each enabling the other (Kitayama & Markus, 1999).

Trusting

Jointly meaningful normative models for relationships direct sociality at interpersonal and intergroup levels, reflecting people's need to know whom to trust and more specific rules for interaction depending on culture; *trusting at least some close others* serves as another core social motive (S. Fiske, 2004; Gurtman, 1992; Yamagishi, 2002).

Trusting Selectively versus Widely

Americans generally have positive expectations about other people, as a baseline (S. Fiske, 2002, 2004). They trust other people in general not to create unprovoked negative outcomes

for themselves. In Japan, trust operates more narrowly, within the ingroup, and only then based on the assurance of knowing the other person's incentive contingencies (Yamagishi, 1998). As a result of the more narrow trusting motive and the embedding of self in a network, caution should be more evident in Japanese data on belonging and rejection.

Our initial cultural comparisons between one East Asian setting (Japan) and an American setting (Yamamoto et al., 2004) entail five kinds of preliminary comparative data: (1) societal stereotypes reflecting rejection between groups, (2) reported norms about rejection among friends, (3) a scenario study about potential rejection, (4) a study of expected interaction and potential rejection, and (5) a study of actual interaction and actual rejection. In each case, we find both cultural similarities and differences reflecting the motive to belong more securely or more loosely (S. Fiske & Yamamoto, 2005). Our initial data suggest that people in the two cultures sometimes have different motives and metaexpectations about interpersonal relationships, although all are highly motivated to belong in relationships and show hurt at interpersonal rejection. Americans' sense of wide, loose belonging apparently fits autonomous understanding, with people being direct and speaking what they view as the truth. They view relationships as a matter of individual choice and control, show self-confidence and self-enhancement, and trust optimistically until their trust is violated.

The Japanese apparently have slightly different motives and metaexpectations. They prioritize social harmony, relation-oriented motives, and do not mind saying different things in different situations. Thus, they do not think feedback is necessarily true, even if their partner evaluates them positively. To the Japanese, one makes positive or flattering statement about another to reinforce solidarity, show respect, and protect the other's "face."

Conclusion Regarding Core Social Motives

Regardless of culture, belonging, understanding, controlling, self-enhancing, and trusting all operate in the context of interpersonal compatibility, with implications for people's well-being in the face of acceptance and rejection. Each culture interprets and transmits ways of enacting these motives in characteristic ways. One venue for enacting these abstract, universal

core social motives is culturally institutionalized relationships, namely social roles.

PEOPLE'S EXPERIENCE OF SOCIAL ROLES: AN ETHNOLOGICAL PHENOMENOLOGY OF INSTITUTIONALIZED RELATIONSHIPS

People often organize their interactions according to institutionalized sets of cultural roles. These roles are explicitly schematized, motivationally salient, culturally elaborated frameworks for social relationships. Anthropologists and sociologists have extensively studied these institutionalized relationships for two reasons. First, these relationships organize everyday intentions and present important constraints, so that people explicitly interpret others' action and justify their own action in terms of these roles. Institutionalized relationships comprise much of the texture of life as experienced—they are among the most salient aspects of the phenomenology, experience, or natural history of sociality. Second, some institutionalized relationships are more or less universal, whereas many others are widespread, so they permit meaningful cross-cultural comparison and analysis. To understand the psychology of everyday social relations, cultural and social psychologists need to recognize these institutionalized relationships and connect their theories to them.

As the second of three ways to describe specific patterns of human relationships, we want to go beyond the range typically considered by social and cultural psychologists to illustrate the varieties of widespread kinds of relationships, none of which is universal, but none is completely particular, either. These 15 types are among those most often culturally elaborated, socially institutionalized, cognitively schematized, and emotionally motivated; thus, they are salient ways of organizing social cognition, motivation, emotion, and evaluation in large subsets of the world's cultures. Surprisingly, no established list or taxonomy enumerates them, but the following are most of the important ones:

- *Marriage*: Close economic coordination and sharing of many significant resources; constitutive of parental relations and often the offsprings' group membership; usually involving coresidence and nearly always some kind of exclusivity in sexual rights. Marriage is virtually

universal, although specific features vary dramatically, notably, how marriages connect groups and create networks, how they are arranged and dissolved, and whether multiple concurrent or successive spouses, or other sexual partners, are permissible for husbands, wives, or both.

- *In-lawship*: Structured, often obligatory relationships with in-laws. In many traditional societies, each kin group “gives” brides to specific kin groups, which entails myriad special norms and practices. These relations are typically asymmetrical: The husband and his kin have economic or labor obligations to the wife’s kin and must be circumspect or avoidant. Conversely, often there is a joking relationship (see the next type of relationship) with the spouse’s younger siblings. (See references below.)

- *Joking and funerary relationships*: A relationship in which the parties are required to tease, insult, roughhouse, and act rudely to each other, usually including sexual jokes or advances. Sometimes participants may freely appropriate each other’s possessions. Partners typically attend each other’s funeral, where they make a mockery of the ritual proceedings and may have responsibilities as executor. Joking partners commonly are defined by kinship roles (e.g., between grandchild and grandparent, or with the spouse’s younger siblings), or relations between pairs of communities or ethnic groups. Widespread across Africa and many other regions, joking relationships are often complemented by avoidance in other relationships in which extreme circumspection is required (typically, especially with one’s mother-in-law) (e.g., Labouret, 1929; Paulme, 1939; Radcliffe-Brown, 1940/1965a, 1949/1965b).

- *Compadrazgo*: The relationship between a person and his or her godchild’s parents. A close, trusting relationship entails lifelong hospitality, aid, and cooperation and precludes sexual relations with the compadre’s spouse. Traditionally, this relationship is universal in the Catholic societies north of the Mediterranean and in many neighboring societies, along with Latin America (e.g., Lynch, 1986; Mintz & Wolf, 1950; Nutini & Bell, 1980; Nutini, 1984).

- *Agemates*: A relationship among men initiated in a particular span of years (typically not at the same event), entailing mutual aid in warfare and raiding, pooling of resources to pay fines, fellowship, and feasting. This usually

requires permissive access to each other’s wives. This relationship, which is present in nearly all the pastoral societies of east and northeast sub-Saharan Africa, is also present in variations elsewhere (e.g., Baxter & Almagor, 1978; Hollis, 1905; Llewelyn-Davies, 1981; Spencer, 1988).

- *Kinship*: Complex constellation of relationships and group membership involving close cooperation and core social identities. Kin usually perceive that they share some essential corporeal essence. Children may belong to the father’s group, the mother’s group, or both. Kinship is important in virtually all cultures and usually is by far the most important organizing framework for sociality. (Some classics include Ember & Ember, 1983; Evans-Pritchard, 1951; Fox, 1967; Lévi-Strauss, 1949/1969; Needham, 1971; Radcliffe-Brown & Forde, 1960.)

- *Milk-kinship*: Close bond between a woman and someone else’s child she has suckled, creating a relationship closely resembling that resulting from birth. This extends to milk-kinship of both parties’ kin. It is important in all Islamic societies, and many other cultures in Africa north of the equator, and the Balkans (e.g., Altorki, 1980; Dettwyler, 1988; Khatib-Chahidi, 1992).

- *Ritual covenant* (“blood brotherhood”): Strong bond of reciprocal altruism, trust, and aid in many cultures created by ingesting or absorbing each other’s blood. This covenant is often formed across ethnic groups, usually between men. Traditionally widespread in Africa and present in many other parts of the world, it usually involves sexual taboos and expectations of partners’ bestowal of a bride (e.g., Beidelman, 1963; Evans-Pritchard, 1933; Tegnaeus, 1952).

- *Reciprocal exchange of prestige goods*: Either simultaneously or alternately, partners give presents to each other, sometimes ritually valuable objects with little or no use value. The standard for the exchange is even matching, but partners may compete to overmatch each other. This custom is famous in Melanesia (e.g., Leach & Leach, 1983; Macintyre, 1983; Malinowski, 1922/1961).

- *Rotating credit associations*: A defined group of people meet at regular intervals. At each meeting, each participant makes an equal contribution to a pool of money, and one person takes the entire pool. The order of turn-taking among the participants may be decided

ahead of time, or by lot on each occasion. The practice is widespread (e.g., Ardner, 1964; Geertz, 1962; Hart, 1977; Vélez-Ibañez, 1983).

- *Sodalities and secret societies*: Ritually constituted voluntary groups that engage in joint activities such as political action, enforcement of morals in the community, or collective ritual or religious responsibilities. This widespread practice is especially common in Africa and Melanesia (e.g., Boas, 1970; Fortune, 1932; Gregor, 1979; MacKenzie, 1996; Mak, 1981; Murphy, 1980; Tuzin, 1984).

- *Castes*: Social categories defined by birth that restrict intermarriage, sexual relations, eating together, or other social contact with lower castes. They are often associated with occupation and nearly always form a status hierarchy. (There is a fuzzy taxonomic boundary between castes and ethnic groups.) Caste systems are widespread (e.g., Bynum, 1992; Camara, 1976; Höffer, 1979; Khare, 1976; Marriott, 1976; Orenstein, 1968; Paulme, 1968; Powdermaker, 1939/1993; Yalman, 1963; Wyatt-Brown, 1982).

- *Slavery*: A relationship in which one person or group owns another, with rights to the product of that person's labor and children, and other controls; usually includes rights to sell the other. The practice has been widespread (including, notably, in classical Greece) (e.g., Kopytoff, 1982; Lovejoy, 1981; Rubin & Tuden, 1977).

- *Prostitution and concubinage*: Sexual acts in return for material considerations. The practice is universal. (For a subtle analysis of these practices in classical Greece, see Davidson, 1998.)

- *Totemic relations*: A group's or an individual's identification with a species of animal (or occasionally a plant species or other natural phenomenon). Totemic groups usually are exogamous (do not marry within the group) and are typically defined by common descent, often putatively from the totem animal. Totemism nearly always entails a taboo against eating the totem, and/or killing it, but sometimes with important ritual exceptions. The practice is widespread; in attenuated form, it is evident in team names and mascots (e.g., Douglas, 1966; Durkheim, 1912/1915; Fortes, 1945, 1966/1987; Frazer, 1910/1968; Goldenweiser, 1910/1963; Tambiah, 1969).

This cannot be an exhaustive list of the most widespread, highly structured, culturally im-

portant types of institutionalized relationships, but it is a start.¹ There are many other widespread types of institutionalized social relationships, most notably, relationships with gods, but most other institutionalized relationships are more variable and culture-specific in form and are therefore less amenable to cross-cultural comparison. To our knowledge, aside from the very different sociological typology of Simmel (1971), there have been no previous attempts to list the most widespread types of institutionalized relationships. In any case, these are many of the major relational schemas for which anthropologists keep an eye out, and whose local nuances are the focus of a lot of fieldwork. At the very least, psychologists may find it a useful glossary for conversations with anthropological colleagues, microsociologists, and informants in other cultures. Moreover, powerful and pervasive social motives, emotions, evaluations, sanctions, cognitive schemas and processes, and much of social action in general are oriented to these institutionalized social relationships. Unless researchers are aware of these institutionalized relationships, they will not understand most of their informants' intentions, evaluations, or obligations.

Theorists have explored factors that may explain the institutionalization of many of these relationship types (see their respective references). But no general theory explains why this set of particular social relationships is institutionalized in a great many cultures. Why do *these* particular 15 role sets tend to diffuse, endure, and become elaborated and institutionalized, in contrast to the innumerable rarer ones that are not often institutionalized? With regard to relational models theory (RMT, covered in the next section), it is intriguing to note that the greatest number of these are primarily communal sharing (CS) relationships; many of the others are predominantly authority ranking (AR) relationships, or ones that combine aspects of CS and AR. In a very few, equality matching (EM) or market pricing (MP) predominate. RMT posits that, in general, the primary intrinsic motivations for relationships differ in typical intensity, with CS > AR > EM > MP. This is one plausible, partial basis for the prevalence of these institutionalized relationships: They meet basic psychosocial needs. For example, the trusting and intimate relationships among agemates, compadres, and ritual covenants are pleasant and rewarding. Joking partners enjoy the teasing and banter. In addi-

tion, it seems likely that many of these institutionalized relationships comprise combinations of relational models that are functionally complementary in some way, at one or more levels. Marriage and kinship effectively organize subsistence activities and material resources, as well as provide necessary frameworks for child-rearing and socialization. Another factor in their prevalence and persistence may have to do with the ways they combine with other relationships. For example, prostitution is clearly related to occupational opportunities for women, together with marriage practices such as male age of marriage, spousal roles, and taboos on sexual relations before marriage, or during pregnancy or lactation. Anthropologists have repeatedly demonstrated how joking partners, ritual covenants, in-laws, and compadres provide crucial alternative economic and political alliances that complement relations to spouses and kin. More generally, to account for the distribution of these institutionalized relationships across and within cultures, we might begin by looking at the manner in which these institutionalized relationships combine with each other, and with more culture-specific relationships. Can we identify a combinatorial syntax of social relationships?

But these are speculations, and cultural psychologists have a virtually open field for exploring the psychological sources of these institutionalized relationships and the psychological consequences of participating in each. The study of institutionalized relationships is an excellent starting point for cultural social psychology, with the notable advantage that they are readily apparent to the observer and well represented in the explicit, reflective, semantic awareness of informants. Moreover, studying them would join cultural and social psychology to their sister disciplines, psychological and social anthropology.

However, there are certain disadvantages of using roles or institutionalized relationships to analyze cultures. Some of these institutionalized relationships are not present in all cultures, and many social interactions in any culture are not shaped by any of them. As we indicated, no theoretical framework encompasses them all, let alone explains them. Nor are they elementary—they are not the basic constituents of sociality. Having considered broad social motives and more specific types of social roles, we now turn to elementary social relationships.

RELATIONAL MODELS

Theory

Relational models theory (RMT) posits that people rely on four elementary models to generate, understand, coordinate, evaluate, and sanction most aspects of nearly all social interaction in all cultures (A. Fiske, 2001, 2002, 2004a). These relational models (RMs) are the basis for most social motives, moral emotions, and evaluative judgments (A. Fiske, 2002). People tend to seek and sustain these four types of relationships largely for their own sake; these relationships are all intrinsically meaningful to varying degrees depending on the RM, culture, gender, age, and individual personality.

Communal sharing (CS) is the organization of interaction according to something socially meaningful that participants have in common (and that differentiates them from outsiders). CS operates when people take joint responsibility for something such as raising a child, when they share resources such as an ocean or food, or when they act with compassion because they identify with another's suffering. CS also underlies the killing of women who besmirch the family's collective honor and the ethnic cleansing of people who pollute the communal purity of the nation. It also operates in collective responsibility, so that an attack on any member of the group motivates other group members to attack any member of the attacking group indiscriminately. CS can be as deep as intense love, or as superficial as sharing access to a drinking fountain or a highway. In abstract terms, CS is a relational structure called an "equivalence group," resembling a categorical scale. With respect to a given interaction, a set of people are either socially equivalent or they are categorically different.

The most intense CS relationships are formed metonymically, when participants' sharing of some aspect of their bodies, or the acknowledgment of something their bodies share in common, creates a categorical bond among the social persons. The process is *consubstantial assimilation* (making their substances similar). In CS, people perceive that their bodies are the same in some way: sharing some essential substance such as "blood" or "genes"; having some crucial surface feature such as (a particular type of) circumcision or skin color; or even moving rhythmically in unison (A. Fiske, 2004b). CS is created and sus-

tained by giving birth, nursing, partaking in each other's blood in bonding rites, and commensal eating and drinking—especially partaking in religious sacrifice. Skin-to-skin contact also promotes CS. Undergoing extreme physical deprivation and peril together likewise creates CS bonds. Prolonged military drill and dancing also tend to have this effect.

Semiotically analyzed, the constitution of CS through consubstantial assimilation is indexical, because the sharing of bodily or co-mestible substances is a material sign of the social relationship: Sharing materializes social cohesion and identification in concrete biologically significant form. For example, people perceive giving birth to a child to cause the CS relationship between mother and child; people perceive blood-bonding covenants to create mutual obligations, because the partners incorporate each other's blood, which binds them morally by connecting their material substance. This constitutive indexicality is congruent with people's communication and cognitive representations of CS as bodily equivalence—that is, people represent the CS connection as same substance, same surface, or synchronous motion. Thus, people *express* CS in the same ways they *create* it, corresponding to the ways they *think* of it. Probably, children also *seek to identify* their CS groups in this way: for example, by attending to who nurses, shares food, holds, and sleeps with them. Conversely, these proclivities for recognizing CS filter its *cultural transmission*. Only those cultural implementations that resonate with these prepared expectations of CS will be readily diffused and repeatedly transmitted. Moreover, whereas any aspect of persons can be equivalent, consubstantial assimilation is uniquely evocative; it motivates and commits people, binding them emotionally.

Authority ranking (AR) structures social interaction in an ordinal hierarchy of asymmetrical relationships. Higher ranking people are entitled to deference and respect from subordinates; subordinates are entitled to pastoral protection from leaders who should stand up for them in dealings with outsiders or higher superiors. AR manifests in status differentiation, privilege, and chain of command. AR includes awe and obedience to superior beings, morality based on the commandments or will of gods and elders, seniority systems, and ranking of people according to achievement or ascription. AR underlies violent contests for dominance

and punishment for disloyalty. Formally, AR is a linear ordering whose meaningful relations and operations correspond to those of a linear scale. Inequality is directional and transitive.

AR is constituted via *social physics*: through space, time, and magnitude (A. Fiske, 2004b). People assume their rank and display it by arranging themselves above and below, or in front and behind; that is, people are ranked as “superiors” and “inferiors,” as “leaders” and “followers.” Higher ranking people come first, or have seniority by being first. Those “higher” in rank are entitled to bigger abodes, bigger shares, and more personal space; they are “greater” than the “little” people who are ranked “lower.” In many unrelated languages, rank is marked by plural linguistic forms, such as the royal “we” or the respectful *vous*.

This social use of space, time, and magnitude is iconic and metaphoric: Relations in space, time, and magnitude are maps of social relations. The linear ordering of positions in any of these physical dimensions corresponds to a linear social rank ordering. This iconic constitution of AR relations reflects a corresponding cognitive representation of AR: People think of rank as position, magnitude, and temporal precedence. Likewise, children anticipate this, searching for these signs of ranking in order to participate in local AR relations. Furthermore, this social physics uniquely evokes the emotions and motives that sustain AR. And communication about AR relies primarily on spatial, temporal, and magnitude representations: The chief is higher, in front of, and bigger than his “subordinates,” and precedes them (he is superior, leads his followers, has precedence, may be addressed in the plural, occupies a greater social and architectural space, etc.). People occasionally invent and impose other media for constituting and conveying hierarchy, but the filter of innate cognitive expectations and affective responses makes space, time, and magnitude the predominant medium of AR in all cultures.

Equality matching (EM) is coordination in which people attend to additive differences, anchored with reference to even balance. In EM, people keep track of whether they are equal, or what needs to be done to make them equal. Examples include taking turns; in-kind reciprocity, such as favors or dinner invitations; tit-for-tat revenge; equal distributions or contributions; and decisions by vote or lottery. In CS, some aspect or resource of the participants is

the same, undifferentiated—"What's mine is yours." In EM, participants are separate but equal; you and I are different but on a par, evenly matched: One person, one vote, and every vote counts, but my vote is not your vote. The relations and operations that are socially meaningful in EM correspond to those defined in an interval scale (formally known as an ordered Abelian group).

People constitute EM with *concrete operations* that *operationally define* even balance (cf. Piaget, 1932, 1952). People are made equal by procedures such as taking turns, drawing straws, or flipping a coin; casting a ballot; lining up on a starting line and commencing simultaneously; beginning and ending work at the same time; counting out shares in rounds of one-to-one correspondence; or comparing shares by aligning them or weighing them in a pan balance. Legitimately conducted, these operations create equality, ostensibly demonstrate it, invoke binding norms, and evoke emotions motivating compliance. Again, the constitutive, communicative, and cognitive systems for EM are congruent with each other and with the processes that mediate children's discovery of the local implementations of EM relations and, hence, their cultural transmission.

Market pricing (MP) structures interaction according to ratios or rates, where all socially relevant aspects of a situation reduce to a common metric. Aspects of an MP interaction frame by proportionality: for example, when morality is framed as justice in due proportion to what each person deserves. Examples include cost/benefit calculations, judgments based on utilitarian rationality, distributions proportional to contributions, and, of course, prices, wages, rents, interest, taxes, and tithes. In MP, multiplication, division, and the distributive law are meaningful because they are in a ratio scale (formally, an Archimedean ordered field).

Abstract, *arbitrary symbols* are the primary medium for constituting and communicating MP. Indeed, cognizing MP proportions, ratios, and rates essentially requires symbolic representation. Displaying a price, making a bid, signing a check, or assenting to a written contract necessarily depend on symbols whose meaning is arbitrarily created by convention. The calculus of cost/benefit analysis and utilitarian morality depends on reducing all values to an abstract numerical metric. The quintessential medium of MP is price (including

wages, rents, interest, fines, etc.), which represents the exchange ratio for a quantity of a commodity against all other commodities in the economy; all features of the object blend into this one number (Simmel, 1900/1990). The reification of prices is the symbol representing prices: money. Contemporary representations of money exhibit its purely abstract, conventional quality: digitally symbolized accounts and transfers that are embodied in no particular material object or place.

Thus people typically constitute, cognize, and communicate each RM in its own, distinctive medium. Children are prepared to discover their community's implementation of the RMs by attending to and trying out these RM-specific media; conversely, these are the channels through which these implementations are culturally transmitted.

To simplify, so that we do not have to refer to all five of the aspects of this constitution–communication–cognition–cultural learning–cultural transmission system every time, we can call this the *conformation system* of the RM: consubstantial assimilation for CS, social physics for AR, concrete operations for EM, and abstract symbolism for MP.

Research

People use these four relational models to make moral judgments, to generate ideologies and political platforms, to give social meaning to land and objects, to exchange objects, to make contributions or distributions, to organize labor, to make group decisions, and to construct social identities. Complex social relationships, groups, activities, institutions, and communities combine models that are sequentially linked, hierarchically embedded, or otherwise concatenated. Every use of any model must be culturally informed, because the models are incomplete: They do not specify with whom, where, when, or how they are to be implemented—or which model is to be used in which aspects of an interaction. Culture provides prototypes and precedents that guide people in applying the models in mutually congruent implementations that permit coordinated action (A. Fiske, 2000).

Wide-ranging research using a wide variety of methods (see Haslam's, 2004, review; A. Fiske & Haslam, 2005) shows that RMs organize three types of naturally occurring social errors in five cultures; people confuse persons

with whom they interact in the same RM. Also, when people intentionally select a substitute for their original partner in an activity, they pick someone with whom they relate according to the same RM. When people list all their acquaintances, they produce runs (clusters) of acquaintances with whom they have the same RM—even though this cannot be a conscious strategy. When asked to sort their acquaintances freely into categories according to how they relate to them, they tend to place people according to the RM that governs their interactions with them. When people judge the similarity of their relationships with others, similarity is a function of whether they use the same or a different RM to relate to the persons. Taxometric studies that use a variety of methods all show that, as theorized, the RMs are psychologically distinct categories, not continuous dimensions. Individual differences in specific patterns of aberrant RM implementations correspond to specific personality disorders. Aberrant implementations of RMs are associated with vulnerability to depression, bipolar disorder, and psychosis. RMT also illuminates organizational behavior and management, political psychology, and the anthropology of the family (reviewed in Haslam, 2004). People detest and derogate explicit framing of trade-offs that apply an illegitimate RM (A. Fiske & Tetlock 1997). The endowment effect results largely from the meaning of objects as mediators of RMs, and the value people place on objects depends on the RMs that the objects are tokens of; that is, the price (if any) at which people are willing to sell an object depends on the social relationship in which they received an object, and the price people are willing to pay for an object depends on the relationship that the object represents for them (McGraw & Tetlock, 2005; McGraw, Tetlock, & Kristel, 2003). The implementation of EM predicts self-enhancement, whereas five measures of individualism do not (Thomsen, Sidanius, & Fiske, 2006). Families and groups get along when they coordinate using the same RM but are frustrated and angry when they attempt to interact using different RMs, or the same RM implemented in different ways (Sondak, 1998; Vodosek, 2003; Goodnow, 2004). (For additional studies and theoretical applications of RMT, see the bibliography at www.rmt.ucla.edu.)

RMs are innate and universal, but their application to organize concrete interactions is

necessarily cultural. According to RMT, cultural variation is the corollary of the indeterminacy of *mods*, the elementary relational structures. For example, children have an innate intuitive understanding of linear ordering in sociality, the AR mod; they cannot innately know who occupies what position in each hierarchy in their community, or in what contexts people are ranked with respect to what aspects of an interaction. Children depend on their culture to provide prototypes and precedents to guide them in implementing AR. To participate in meaningful, coordinated interaction, children have to implement each RM in accord with the specific cultural prototypes and precedents that others in their community are using. Relational mods cannot be implemented in their abstract, indeterminate, innate form: They must be implemented in specific, culturally informed coordination systems. Culture provides *preos* (precepts, principles, precedents, and prototypes) that complement and complete innate but indeterminate relational mods. Children learn these preos through the conformation system in which they are culturally transmitted, mentally cognized, and communicated in everyday representations.

RMT posits that humans are innately sociable: They seek to form and sustain relationships largely as intrinsic ends in themselves. Children and adults have innately structured motives specific to each RM. People need CS relationships especially, but also AR and EM relationships. To a lesser degree, they may also sometimes need MP relationships. Of course, individuals differ in the strength of these motives, and cultures differ in which motives they recognize, legitimate, foster, suppress, or redirect; cultures also differ in where they orient each motive. In an African village, people meet most of their CS motives within permanent kin relationships and some enduring friendships; in an American city, the middle-class seeks to meet its CS needs in (often impermanent) romantic dyads, as well as friendships and associations.

RMT posits that RMs coordinate most mutually meaningful social relationships. Of course, people do not have meaningful social relationships with most other people. Indeed, people may be present in the same space, or causally affect each other, without participating in a meaningfully coordinated relationship. If they simply ignore each other's sociality, ig-

noring each other's existence or treating each other like nonsocial objects, then we say they have a *null* relationship. For example, a forager gathers the fruit from a tree without concerning herself about any other person's potential rights to that fruit, so she has a null relationship with those others. Likewise, if bullets are flying, I seek cover behind a log or a body; I treat the body as merely a shield like the log, having a null relationship with the log and—in the moment, at least—with the person whose body it is, even if the person later turns out to be alive.

If a person attends to the other's sociality but is not guided, motivated, or obligated by any RM—although aware that the other's cognition and motivation *is* socially organized—that person's orientation can be characterized as *asocial*; that is, the orientation is asocial if the other person is nothing but a means to nonsocial ends—if a relationship with the other is neither intrinsically motivated nor felt to be morally binding. Psychopaths are asocial, and pure Machiavellianism is asocial.²

RMT is a comprehensive synthesis of major theories of sociality, but it differs from other theories in several respects. First, several other major theories, such as Tönnies's contrast of *Gemeinschaft* and *Gesellschaft*, or Durkheim's mechanical versus organic solidarity, have described a subset of the four basic types of relationships but left out one or two of the basic forms. Although a few other theories have recognized all four basic forms of sociality in one particular domain of social life, RMT is the only theory that encompass all domains of social coordination and shows how the same RMs operate across domains. No other approach provides a unified theory of interpersonal, intergroup, organizational/institutional, and international coordination. RMT connects ideology, economy, and polity to social psychology and to many forms of psychopathology. RMT also uniquely integrates social cognition, communication, constitution, cultural transmission, and children's social development, along with social emotions, motives, moral judgments and values, sanctions, and the maintenance, redress and repair, and termination of social relations. No other general theory of sociality incorporates into the same framework universals, individual differences, and variation across cultures. Moreover, RMT aims, at least, to formulate an integrative understanding of the mechanisms and processes of natural selection, neuroanatomy, neuro-

physiology, ontogeny, and culture that shape social relations—and are in turn shaped by social relations. Also, RMT is one of the few theories that recognizes that humans have evolved to be intrinsically social. Moreover, RMT sees children as sophisticated, active culture seekers. The development of sociality is not just socialization or internalization, it is a process of externalization in which children strive to connect their innate social proclivities—the four mods—with the local cultural implementations—preos. Cultural prototypes and precedents complement and complete children's innate relational proclivities, coming together to form definite models for social coordination.

Nevertheless, RMT has some major limitations. As currently formulated, RMT does not address the long-term ecological, societal, and functional factors that affect which RM coordinates which domains in which cultures and *how* RMs are implemented; nor does it explain how implementations change historically. Nor does RMT address the situational, demographic, and strategic factors that affect people's choice of RMs and their implementations when they have a cultural choice, at the margins. Furthermore, RMT does not explain what goes on outside the framework of RMs, or before people adopt an RM; that is, it does not encompass cognition, motives, or emotions in either null or asocial relations. This is just what the social-cognitive content model (SCCM) covers—including the ways that people cognize persons as potential relational partners. Both RMT and SCCM posit that humans are fundamentally social beings with strong relational needs; SCCM addresses the ways in which cognition about persons serves core social motives.

SOCIAL-COGNITIVE CONTENT MODEL: AN EXPANSION OF THE STEREOTYPE CONTENT MODEL

Theory

When people respond to another social entity, whether a group or an individual, they do so in the service of core social motives. The motive to belong is central; it is the motive for seeking to form or join CS relationships (A. Fiske, 2002b; S. Fiske, 2004; Leary & Baumeister, 2000). People want to connect with other people in their own group, arguably, to survive and thrive. The core motive to belong defines ingroup (own group) and outgroup (all other groups). Ingroup *belonging* matters because

the ingroup by definition shares one's goals, which facilitates other core social motives, as described earlier—socially shared *understanding*, a sense of *controlling* one's outcomes, *enhancing* the self, and *trusting* close others (S. Fiske, 2004). The outgroup by definition does not share the ingroup's goals, and is at worst indifferent and at best hostile, so the outgroup is viewed as threatening and elicits negative affect (S. Fiske & Ruscher, 1993). This approach to social behavior highlights the importance of knowing who is with "us" and who is against "us," in the service of furthering shared goals. The approach has elements in common with other emphatically social adaptational perspectives on social cognition (e.g., Kurzban & Leary, 2001; Neuberg, Smith, & Asher, 2000), but it focuses less specifically on reproductive strategies and more on social surviving and thriving within a group. People are demonstrably healthier if they are not socially isolated. This approach also fits a pragmatic, goal-based analysis of social behavior (S. Fiske, 1992). In this view, social perception provides the foundation for social survival within one's group. Some principles are universal, although their instantiations vary by culture, as we will see.

If the core motive of ingroup belonging matters so much, then people's central concern when encountering another person or group will be the other's group membership; that is, in RM terms, the CS group(s) to which the other belongs. Previous theoretical work and research on the continuum model show that such social category-based responses are rapid and primary, coming before more individuated, person-specific responses (e.g., S. Fiske & Neuberg, 1990; S. Fiske, Lin, & Neuberg, 1999). Our subsequent and current work more closely examines the nature of these social categories. We proceed from the premise that the crucial categories essentially answer: friend or foe? And then: able or unable? That is, when people encounter strangers, they first want to know the strangers' intentions (good or ill) and their ability to enact them (capability). If the intentions are good, then the social other's goals are at least compatible, and the other is ingroup or a close ally. Otherwise, the other is threatening. And whether the goals are compatible or not, people want to know whether the other actually matters (if capable) or not (if incapable).

The stereotype content model (SCM; S. Fiske, Xu, Cuddy, & Glick, 1999; S. Fiske, Cuddy, Glick, & Xu, 2002) proposes that soci-

etal groups are universally perceived along two primary dimensions, warmth and competence. These are the two primary dimensions of general stereotype content. *Warmth* is anchored at the positive end by characteristics such as friendly, good-natured, warm, and sincere: Is the other friend or foe? *Competence* is anchored by characteristics such as capable, confident, competent, and skillful: Is the other able or unable? Perceived warmth occurs in relation to society in general (Group X is or is not nice people in general) but also in interpersonal relationships (Person X is always nice or not nice to me). Perceived competence occurs in relation not only to society in general (valued skills) but also to specific relationships contexts (relevant skills). People tend to conflate these two levels, believing that their experience, or their group's experience, represents the true nature of those other social entities.

Related Research

The two dimensions have received copious support from several areas of psychology. These dimensions emerge in classic American person perception studies (S. Fiske, Cuddy, & Glick, 2007). And in more recent Western person perception research, these two dimensions account for more than 80% of the variance in global impressions of individuals. Similar twin dimensions appear in European work on social value orientations, in construals of others' behaviors, and in voters' ratings of political candidates in the United States and Poland. Related dimensions also describe Western national stereotypes (e.g., competence and morality); and emerge in analyses of prejudices toward many specific social groups in the United States and Europe (e.g., S. Fiske et al., 2007).

These two dimensions differ from two other broad frameworks that might at first seem similar. First, the semantic differential dimensions of evaluation, potency, and activity (Osgood, Suci, & Tannenbaum, 1957) do not correspond, because both warmth and competence entail evaluation (better to be high on both); moreover, both vary in the potency and activity of their expression. Second, the perceived warmth and competence dimensions correspond to people's impressions of others, whereas the Big Five personality traits (Extraversion, Agreeableness, Conscientiousness, Openness to Experience, and Neuroticism) correspond to measured consistency in

behavior (Wiggins & Trapnell, 1997). People do not necessarily perceive each other along five dimensions, but may opt for a more pragmatic sense of their social relationship, based on intent (warmth) and ability to enact it (competence).

Evidence from the United States

The SCM proposes that stereotype contents respond to fixed principles that apply across varied perceivers and groups. In the United States, stereotype content and its social structural correlates are systematic, generating three fundamental hypotheses (S. Fiske et al., 1999, 2002). First, across groups, *stereotypes share common dimensions of content: warmth and competence*. Second, *many outgroups receive evaluatively mixed stereotypes*: more positive on one dimension and less positive on another. Third, locations of groups along *these dimensions of stereotype content follow from social structural variables*: Perceived status predicts stereotypical competence, and perceived competitiveness predicts stereotypical (lack of) warmth. The SCM maps stereotypes, and a group's location on the map results from its place in the social structure.

Previous U.S. datasets (S. Fiske et al., 1999, 2002), including a representative sample survey (Cuddy, Fiske, & Glick, in press-b), have mapped several dozen American groups (e.g., poor people, rich people, old people, middle-class people, disabled people, Asians, Jews). The groups reliably differentiate in this two-dimensional space of liking (warmth) and respecting (competence); that is, they spread out in all quadrants of the space, and cluster analyses typically identify clusters in each quadrant of the space. These findings support the first hypothesis, common dimensions.

To investigate the second hypothesis, that many stereotypes rate differently on warmth and competence, we examined the distribution of the groups in the map of outgroups. Only a few groups land in the most obvious, unmixed combinations of liking and respect (pride-inspiring groups such as Christians and the middle class) or disliking and disrespect (contempt-inspiring groups such as the homeless and poor). The interesting combinations are mixed and elicit ambivalence: Liked but disrespected, the pitied groups are high on perceived warmth but low on perceived competence (e.g., older, disabled). Conversely, the envied, disliked but respected groups are low on

perceived warmth but high on perceived competence (e.g., rich, Asian, Jewish). Many of the groups, often the majority, land in the mixed competence \times warmth quadrants, high on one and low on the other, as predicted.

Much additional support for the mixed stereotypes hypothesis—that many groups are perceived as high on one dimension but low on the other—stems from research on stereotypes of specific social groups. Two types of stereotyped groups materialize in this literature: those viewed as kind but helpless, and those viewed as skillful but cunning. Envious prejudice is directed at the latter groups, who are seen as threateningly competent and untrustworthy (Cuddy, Fiske, & Glick, in press-a; in press-b). For example, “nontraditional” women, such as career women and feminists, are perceived to possess agentic but not communal traits, and are respected but disliked—the embodiment of envious prejudice. Envious prejudice also targets Asian Americans, who are characterized by stereotypes such as excessive competence (too ambitious, too hardworking) and lack of sociability. Similarly, stereotypes of Jews combine business acumen with interpersonal self-interest. Viewed grudgingly as worthy of respect, such groups are not well liked, and they elicit envy, a loaded emotion that involves both hostility and depression. Envy tends to be directed toward higher-status people when their standing is seen as unjustly gained.

Groups seen as benevolent but incapable of competing in mainstream society sit in the opposite corner of the map. This type of prejudice reflects liking but disrespect and often targets traditional women and elderly people, both perceived as high communal but low agentic (Cuddy et al., in press-a, in press-b). Viewed as harmless but pathetic, they typically elicit pity, a paternalistic response. Pity goes to individuals whose stigmas are viewed as uncontrollable and to lower-status people (Cuddy et al., in press-a, in press-b).

Still, some groups receive evaluatively consistent stereotypes. Groups whose members are perceived as both hostile and indolent are most susceptible to the traditional form of antipathy normally associated with derogated groups. These groups elicit contempt (S. Fiske et al., 2002) that tends to be directed toward stigmatized people whose negative outcomes are perceived by others as avoidable. For example, homelessness, obesity, and AIDS all elicit anger, but only when attributed to individual weak-

nesses or moral shortcomings. Welfare recipients and poor people of any race also elicit disgust and contempt more than any other quadrant's groups (S. Fiske, Cuddy, & Glick, 2002).

Conversely, ingroups and mainstream social groups are favored as both warm and competent. These groups typically elicit pride and admiration (S. Fiske, Cuddy, & Glick, 2002), apparently because of their valued attributes that reflect on but do not detract from the self. All four of these patterns—for ingroups, extremely negative outgroups, and the two mixed types of groups—support the frequency of evaluatively mixed stereotypes, the SCM's second hypothesis.

In keeping with the SCM's third major hypothesis, different locations in the social structure—high or low status, more or less competition—predict intergroup stereotypes, emotions, and behaviors. Status and competition both operationalize relative to society in general. People report how groups are viewed by society, and their own relative position does not much affect their knowledge of where groups stand relative to each other. People respond in much the same ways to individuals of higher and lower status who compete or not with them as individuals (Caprariello, Cuddy, & Fiske, 2004; DiChiara & Fiske, 2004).

Focusing on the friend-foe dimension, competition reliably predicts a perceived lack of warmth. Groups perceived to compete with the ingroup or with society in general (e.g., by being exploitative) are seen as unfriendly. The evidence reviewed in the next section shows that this effect is reliable, though moderate in size.

Also, status reliably predicts perceived competence. People apparently endorse meritocracy more than sour grapes: Groups get what they deserve. The research reviewed in the next section shows that this status-competence effect is large and robust.

Evidence from Europe and from East Asia

The SCM previously had been tested only in U.S. samples. If the SCM describes universal human principles, then they should not be limited to American perceivers or other culturally related contexts. Although it proposes systematic principles of societal stereotypes and their relation to social structure, some aspects should be culturally variable. In this research (Cuddy, Fiske, Kwan, et al., in press), the SCM revealed theoretically grounded cross-cultural,

cross-group similarities and differences across 10 nations. Student samples ($N = 1,028$) from seven European and three East Asian samples (Japan, South Korea, and Hong Kong) supported three hypothesized cross-cultural similarities: (1) Perceived warmth and competence reliably differentiate societal group stereotypes; (2) many outgroups receive evaluatively mixed stereotypes; and (3) high-status groups stereotypically are competent, and competitive groups stereotypically lack warmth.

Our comparative data uncovered one consequential cross-cultural difference: The three East Asian cultures did not locate their own reference groups (ingroups and societal prototype groups) in the most positive cluster (high-competence/high-warmth). Most discussions of prejudice (e.g., Brewer & Brown, 1998; S. Fiske, 1998) hold that outgroup derogation requires obvious reference-group favoritism. But although the East Asian samples showed less self-enhancement and diminished reference-group favoritism, they apparently did so without eliminating outgroup derogation. This, on a societal level, is analogous to modesty with regard to the self, a phenomenon frequently observed in East Asian samples compared to Western ones (Markus & Kitayama, 1991).

The different SCM quadrants elicit not only different stereotypic traits and distinct emotional prejudices but also specific patterns of discriminatory behavior, resulting in the Behaviors from Intergroup Affect and Stereotyping (BIAS) map (Fiske, Cuddy, & Glick, 2002). As noted earlier, people are proud of or admire high-competence, high-warmth ingroups and reference groups; this elicits helping and association. Low-competence, low-warmth outgroups receive contempt and disgust, which elicits both active harm (attack, fight) and passive harm (exclude, demean).

Two evaluatively mixed clusters receive ambivalent emotions and behavior: People report envy and jealousy of high-competence but low-warmth groups, which elicits both active harm (sparked by dislike) and passive association (because of their high status). Low-competence but high-warmth groups receive pity and sympathy, which elicits both passive harm (sparked by disrespect) and active help (because they pose no threat). These behavior predictions are supported in the U.S. national survey data, as well as student samples (Cuddy et al., in press), but they await cross-cultural comparison.

The SCM applies to the perception of individuals as much as groups, and even to the percep-

tion of individuals not perceived as group members per se; that is, the same structural features (status and competition) that predict impressions of groups (stereotypes and emotional prejudices) should predict impressions of individuals. In recognition of this prediction and of its origins in person perception research, we refer to the overarching principle as the SCCM. We would expect the general principles of the SCCM to be culturally universal. For example, in the American case, the self and close friends (allies) would appear as warm and competent. Across many cultures, people prefer friends and mates with a few specific traits that fit the generality of this prediction, namely, kindness and intelligence (Buss, 1989; Buss & Barnes, 1986). Various SCCM aspects, but especially those involving self, might again show cultural variability, as has been demonstrated for the SCM.

The Social-Cognitive Content Model

The expanded SCM, termed the SCCM, suggests that for adaptive purposes, people need to know immediately whether other social entities (individuals, groups) are with them or against them, as in the sentry's call, "Who goes there? Friend or foe?" Upon knowing the other's intent, a secondary question is the other's competence to enact that intent (the sentry wants to know whether the other is armed). The SCCM emphasizes dimensions that indicate the nature of the perceiver's interdependence with others. But cultural enactments of belonging in relationships differ, for example, along dimensions of belonging securely to a few, stable, long-term relationships or many, unstable, shorter-term relationships. The core motives approach that emerges in the SCCM demonstrates again that universals and cultural particulars are products of the same adaptive system by which people survive and thrive within social relationships.

RSVP: RELATIONAL STRUCTURE, VALENCE, AND PULL

Relating SCCM and RMT

SCCM is a theory of the perception and evaluation of persons and groups, especially when no concrete relationship has (yet) been established between the perceiver and the target persons. It describes structural relations between groups in society, and the members of these groups, on the basis of relative status/power and their

competition or cooperation. RMT is a theory of structures for coordinating and evaluating interactions, when such normative coordination occurs. Processes at the SCCM and RMT levels are connected, because the perception of strangers, distant acquaintances, and groups is predominantly oriented toward anticipating the nature of the potential relationship that might be formed with them. People need to know how they are going to coordinate if they start to interact with the person(s) they are perceiving; moreover, they want to decide whether to engage or to avoid engagement. So people think about others primarily as potential relational partners (A. Fiske & Haslam, 1996). Conversely, based on their experience in relationships they do form, people engaged in any RM evaluate their existing and former partners on dimensions of warm to hostile, and competent to incapable.

Furthermore, RMT and SCCM readily connect, first because they each address both individual and group levels of analysis. RMT posits that the four RMs organize relations among groups and relationships of persons to groups, as well as among individuals (A. Fiske, 1991, 2004a). Similarly, SCCM posits that the dimensions that underlie perception of groups also underlie perception of individuals in status and competition structures.

Second, the two models cover a range of intensity, defined here as "pull." Pull is related to attractiveness, or rather, motivation to relate to the other. Pull is the *desired amount* of relationship: the depth, breadth, and duration of sociality that people seek with a given individual or group. RMT posits that any of the four RMs can be implemented at any intensity; a relationship can have any level of *pull*; that is, any type of relationship can encompass any extent, frequency, duration, and range of interactive domains, and can involve any level of motivation and normative obligation.³ The limiting case, where pull is zero, is a null relationship, in which people do not use any RM to evaluate or sanction any aspect of their interactions (A. Fiske, 1991). Lacking any impetus to engage in a coordinated relationship, people respond to others primarily according to their perceived warmth and competence, the SCCM dimensions.

Relationship Priorities

People usually prefer warm relationships to hostile relationships. Furthermore, competent

people are able to make things happen, and are hence attractive relationship partners—people want to connect with them—provided they are not perceived as likely to be hostile. So the greater the competence and the warmth of each potential participant in a prospective relationship, the greater the disposition of other potential participants to form a relationship with them, and then to extend, intensify, and deepen the relationship; that is, warmth and competence predict pull (attraction). The other's competence and warmth relevant to self interact in their positive effects on relationship pull, because the greater someone's competence, the more the person can do for and with you, if so inclined. Conversely, hostility and competence interact in their negative effects on relationship pull: A competent person can do you a lot of harm, if so inclined. So, overall, we predict the following ordinal scale of relationship pull (the motivation to relate intensely):

Competent + Warm > Incompetent + Warm >
Incompetent + Hostile > Competent + Hostile

Although warmth enhances all relationships, making them function better, warmth is not equally important in all four RMs; for different relationships, the consequences of warmth differ. Note that we do not equate warmth with CS; any relationship can be warm (friendly, nice, sincere, and trustworthy), and CS relationships need not *necessarily* be warm; people may share a public park or a highway without being warm. Nevertheless, warmth is most crucial to CS relationships, important in AR (both up and down), variably but generally less crucial in EM, and an important basis for trust in MP, but not essential so long as there are external enforcement mechanisms. Conversely, it seems likely that the intrinsic rewards of the RMs vary considerably, so that people find some types of relationships more satisfying than others, and hence warmer. The order of intrinsic reward is also CS > AR > EM > MP.

Likewise, although competence has an impact on all relationships, the consequences of competence differ for different RMs. Competence is crucial to MP and also fairly important in EM. Competence is less important in CS—people love babies and may loyally tend to totally incapacitated sick and elderly partners. In AR, there is an asymmetry: People demand high competence in their superiors but tolerate lesser competence in their subordinates. Indeed, when status is achieved (vs. ascribed), rel-

evant kinds of competence *result* in higher status. The effects on pull can be summarized as follows:

Importance of Warmth: CS > AR > EM > MP

Importance of Competence: MP > EM > CS

Higher AR > Lower AR

But the causal processes operate not only from valence (warmth, competence) and pull (attractiveness) to RM but also in the other direction. SCCM theorizes that people perceive social superiors as competent; in an AR relationship, people perceive those above them as competent and those below them as incapable. In 13 worldwide student and adult samples, the status–competence correlation averages .89 (Cuddy, Fiske, Kwan, et al., in press). Putting SCCM and RMT together leads to the prediction, as yet untested, that status will be most highly correlated with perceptions of competence in just the domains where AR operates in a given culture; that is, people are ranked in some social domains but not others, so they will perceive the greatest competence differences in abilities that operate in those domains compared to abilities related to cultural domains in which AR does not operate.

SCCM also theorizes that people perceive competitors as hostile (correlation averages .25). Competitors are people whose goals or interests are mutually exclusive with self, putting them at odds with each other. Competition divides people, precluding CS relationships. The opposite of competition is having a shared interest in attaining mutually interdependent aims, where each person can only get what he or she seeks if the other person does too. This means that they have important outcomes in common—they have some kind of CS relationship. For this reason, and because of the intrinsically rewarding nature of CS, we posit that CS relationships generate warmth. However, violation of a CS or AR relationship often instantly transforms warmth into extreme hostility. To summarize:

AR → Competence differentiation:

Higher status → higher perceived competence in abilities related to the ranked domain,

Lower status → lower perceived competence in abilities related to the ranked domain.

CS → Warmth, but

Violation of CS or AR → Hostility.

What about EM and MP? Do they affect perceptions of competence and warmth? Both can be implemented as frameworks for competitiveness, that is, as the starting point for comparative AR. Indeed, competitiveness may even enhance performance in EM and MP: Games, sports, or election contests and other rivalries are structured by EM, whereas competition among buyers and among sellers makes MP systems efficient. Sometimes this competitiveness develops into hostility, but excessive hostility is not conducive to functional EM or MP. On the contrary, a background presupposition of a sufficient level of warmth, or at least trust based on shared interests in sustaining functional cooperation, facilitates both EM and MP.

MP tends somewhat to enhance perceptions of competence. MP is linked to division of labor and consequent specialization, resulting in specialized competence, such that each party is uniquely competent in its own specialty. EM can work either way. When implemented as the framework of rules that establishes the conditions for a contest, EM often results in an assessment of relative competence that enhances perceptions of the competence of the victorious competitor and diminishes the perceived competence of the loser. When each side attempts to humiliate the other side by outdoing it, even turn-taking can be a contest with this effect. But when implemented as balanced equality in performance, EM tends to result in a leveling sense of evenly matched competence—provided all parties adequately carry out their turns. In short, when acting within an EM framework, failing to match others results in evaluative derogation and attribution of incompetence.

In short, dynamics go from not only valence (warmth, competency) to pull (attraction) and type of relationship but also in the other direction, from RM to valence and pull. Integrating RMT with SCCM produces a theory that we call relational structure, valence, and pull. *Répondez s'il vous plaît* means “please respond,” so RSVP is an apt name for a theory that highlights how people respond to each other. RSVP posits that valence (warmth and competence together) strongly affects pull—people’s desire to form and intensify relationships. Conversely, relationships structured according to each of the four RMs have distinctive effects on perception of the warmth and competence of relational part-

ners, and the pull to intensify or withdraw from the relationship.

RSVP also goes beyond either SCCM or RMT, because it extends both and connects them, providing a more comprehensive characterization of the aspects of sociality that determine action and affect. RMT has nothing to say about how people cognize or evaluate others before they form a relationship, but SCCM characterizes the fundamental dimensions of cognizing and evaluating others in this presocial state. SCCM has nothing to say about how interpersonal relationships are structured, whereas RMT characterizes the fundamental structures for coordination.

When people relate to each other, there is more to the interaction than can be captured by the quantitative warmth and competence dimensions. But there is also more to a relationship than can be captured by its relational structure alone. RSVP posits that the key attributes that determine the nature of a social relationship are the *relational structure, its valence, and its pull*.

Metatheoretical and Methodological Issues in Cultural Comparisons

For more than two decades, cultural psychologists have relied on a comparative schema based on the constructs of individualism and collectivism or independence and interdependence (A. Fiske et al., 1998). Indeed, this contrast goes back to the foundation of social science in the work of Tönnies (1887/1988) and Durkheim (1893/1933). However, recent work questions these constructs, so we do not use them here. Different measures of each construct neither correlate with each other nor yield the same classification of cultures (A. Fiske, 2002). Although individualism and collectivism were originally theorized to be polar opposites (Hofstede, 2001), measures of the two constructs are generally orthogonal (Oyserman, Coon, & Kimmelmeier, 2002). Measures of individualism do not correlate with the key constructs they were theorized to be functionally tied to, such as self-enhancement (Thomsen et al., 2006). Moreover, both constructs lump all social relationships together, positing that their motivational and cognitive importance covary: Either all relationships are more important than “individual” goals, or all are less important than individual goals. The ethnographic evidence

indicates, on the contrary, that social relationships are crucial in all cultures, but that *different* relationships are salient in different cultures—and that elementary relational models are implemented differently according to cultural prototypes. The construct of “individualism” bundles together a disparate set of features that happen to be historically prominent in contemporary Western ideological constructions of modern Western society, contrasting them with the supposed “collectivism” of societies whose only common feature is that they are not modern and Western.

Perspectives

Cultural psychology has focused on cognitive differences between cultures, because it arose largely from the realization that cognitive processes previously thought to be universal in fact vary as a function of culture. We need to pay more attention to explaining *why* this variation exists at all—why are human sociality and cognition so diverse? What is it about the human psyche that makes it depend on culture? The uniquely human adaptive advantage consists of linked capacities to learn from others and to flexibly and rapidly adapt social relations to utilize diverse and changing ecological niches. This social learning and relational flexibility result in cultural diversity. Yet we still know little about how this cultural transmission occurs.

To be cultural, psychology has to explain how people become proficient, motivated participants in the particular social networks into which they are born or later enter; that is, cultural psychology must explain how people develop into culturally informed beings and continue to acculturate. In this chapter we have described a wide range of institutionalized relationships, as well as four types of RMs. We have posited that children are intrinsically motivated to form relationships, and that they expect to find the cultural cues for these social relationships in distinct media corresponding to the type of relationship: bodily assimilation for CS; above, in front, earlier, greater, or stronger for AR; concrete operations that are ostensive procedural definitions for EM; and abstract conventional symbols, such as money and utility, for MP. These are the media in which humans are prepared to constitute and communicate social relationships, and in which they cognize them. These are the channels through which cultures transmit their prototypes and

precedents for implementing RMs. Moreover, these are the modes of action that evoke relational motives and invoke normatively binding social commitments.

Children also learn to relate to different kinds of strangers and evaluate ingroup members based on perceived intent (cooperative–competitive) and status, inferring respectively the others’ warmth and competence. The pull (attraction) of a relationship depends on warmth–competence combinations and on whether it is a null relationship or a developed RM. Each RM can be implemented in different ways, resulting in distinctive evaluations of relational partners as warm or hostile, capable or incompetent. Social relationships are intrinsically motivated, fulfilling basic relational and other needs; the intensity, form, and orientation of these needs are inevitably shaped by the prevalent social experiences in each culture, but all humans are fundamentally relational animals. Yet every human is necessarily social in a distinctive, culturally informed manner.

NOTES

1. We thank Nancy Levine for her comments and a couple of additions to this list.

2. Cultures, types of relationships, specific relationships, and individuals seem to vary in the degree to which the identity of the particular partner is important to the relationship. Parsons described aspects of this issue in terms of his universalism versus particularism pattern variable (Parsons & Shils, 1951; Parsons & Bales, 1955). Americans regard the identity of their spouses as fundamental to their marriages; on the other hand, one customer can substitute for another pretty easily, or one grocer for another, without much consequence. However, some American MP relationships are very dependent on the particular identities of the partners; there are no good substitutes. Levy (1973) discovered that, compared to people in many cultures, Tahitians were much less concerned about the identity of the children in their home; people often request and grant fostering rights to others. Likewise, although not indifferent, Tahitians are comparatively unconcerned about *who* their lover or spouse is; what is important is to have one, and whereas some are better than others and one gets used to a particular person, it does not have to be anyone in particular. Pham (2006) showed that cultures differ in whether they focus on sustaining existing relationships or forming new ones.

3. These components of pull appear to be analytically distinct, but at this point we think that parsimony is more important than conceptual discrimination, so for now we collapse them into one dimension, pull.

CHAPTER 12

Culture and Social Identity

MARILYNN B. BREWER
MASAKI YUKI

The concept of “social identity” has been invoked throughout the human sciences whenever there is need for a conceptual bridge between individual and group levels of analysis. Social identity provides a link between the psychology of the individual—the representation of self—and the structure and process of social groups within which the self is embedded. As a consequence, the social identity concept has been invented and reinvented in a wide variety of theoretical frameworks, and across all the social and behavioral science disciplines (Brewer, 2001; Stryker, 1987; Thoits & Virshup, 1997).

The ubiquity of social identity theory and research throughout the social sciences reflects some universal features of human society that derive from the profoundly social nature of human beings as a species. Group living is part of human evolutionary history, inherited from our primate ancestors but evolved to a level of interdependence beyond that of any other social primate (Brewer & Caporael, 2006; Caporael, 1997). With coordinated group living as the primary survival strategy of the species, the social group in effect provided a buffer between the individual organism and the exigencies of the physical environment. Given the morphology and ecology of evolving hominids, the in-

terface between hominids and their habitat must have been a group process. Finding food, defending against predation, moving across a landscape—these matters of coping with the physical habitat—are largely group processes. Over time, if exploiting a habitat is more successful as a collective group process than as an individual process, then not only would more successful groups persist, but so also would individuals who were better adapted to group living. Thus, we would expect that the basic elements of human psychology—cognition, motivation, and emotion—would be attuned to the structural requirements of social groups and social coordination.

The capacity for social identification—considering the self as a part of a larger social unit—is one feature of human psychology that serves to regulate and maintain the essential relationship between individuals and their social groups. In all societies, individuals view themselves as part of defined social groupings (*ingroups*) characterized by mutual cooperation and reciprocal obligation (Levine & Campbell, 1972; Sumner, 1906). Although the capacity for social identity is postulated to be universal, the locus and content of social identities are clearly culturally defined and regulated. Thus, social identity provides a rich area

for study of the interface between individual psychology and systems of cultural practices and meaning.

The study of cultural differences in social identification is most often couched in terms of the distinction between *individualism* and *collectivism* as one basic dimension of cultural norms and values (Hofstede, 1980; Triandis, 1989; 1995). As it is most generally understood, individualistic cultures are characterized by an emphasis on autonomy and differentiation of the individual self from others, whereas collectivist societies are characterized by social embeddedness and interdependence (Oyserman, Coon, & Kimmelmeier, 2002). In terms of self-definition, individualists are assumed to focus primarily on the distinction between self and others (me vs. not me) and collectivists on the distinction between ingroup (us) and outgroup (them), with little differentiation of the individual self within the ingroup. As a consequence, collectivists are expected to show high levels of ingroup–outgroup discrimination in their social behavior, whereas individualists are expected to be more universalistic and nondiscriminatory. In terms of goals and values, individualists give priority to personal goals over the goals of collectives, whereas collectivists either make no distinction between personal and collective goals, or if they do, they subordinate their personal goals to collective goals (Triandis, 1989). With regard to ingroup identity, the central theme of individualism is the conception of individuals as autonomous beings who are separate from groups; the central theme of collectivism is the conception of individuals as aspects of groups or collectives (Triandis, Chan, Bhawuk, Iwao, & Sinha, 1995).

Given the universal requirements of group living and social interdependence, we believe that this bipolar characterization of culture anchored by individualism at one end of a dimension and collectivism on the other is too simplistic. And, indeed, the representation of individualistic societies described earlier is inconsistent with decades of research on social identity and ingroup bias that has been conducted almost exclusively in highly individualistic Western societies (cf. Brewer, 1979; Tajfel & Turner, 1979; Abrams & Hogg, 2001). Furthermore, a recent comprehensive review of cross-national studies of individualism and collectivism (Oyserman et al., 2002) indicates that Americans (who generally score high on measures of individualism) are found to be no less

collectivistic than East Asians (particularly Japanese and Korean) on several components of collectivist values and attitudes.

We do not doubt that societies differ in terms of degree of individualism, specifically, the extent to which a culture emphasizes independence and autonomy over interdependence and harmony (Markus & Kitayama, 1991; Oyserman et al., 2002; Schimmack, Oishi, & Diener, 2005). What we challenge is the notion that individualism precludes social identification with social groups and collectives. In our view, a more complete understanding of cultural differences in social identity will start from the recognition that *all* societies must meet primary needs for both individual and social identity, and provide for an effective interface between individual self-interest and collective interests and welfare. What differs across cultures is *how* social identification processes are represented and channeled to regulate social cooperation and achieve a balance between expression of individuality and social conformity (Brewer & Roccas, 2001). We present a thesis that complements previous work on individualism and collectivism by showing how societies that are traditionally classified as collectivistic differ from more individualistic societies in the nature and structure of social identities. In this chapter we hope to elucidate the role of culture in shaping (1) the meaning of ingroups, (2) the relationship between group identity and trust, and (3) the nature of ingroup–outgroup biases.

SOCIAL IDENTITY THEORY: BASES OF INGROUP IDENTIFICATION

Within social psychology, the most elaborated theory of social identity and ingroup bias is social identity theory (SIT), as developed by Tajfel and Turner (1979), and the related self-categorization theory (SCT), developed by Turner and colleagues in subsequent years (Turner, Hogg, Oakes, Reicher, & Wetherell, 1987). Thus, we begin our review with a synopsis of SIT and related research, then show how the introduction of a cultural perspective leads to qualification and modification of the theory.

Social identity is defined as “that part of an individual’s self-concept which derives from his knowledge of his membership of a social group . . . together with the value and emotional significance attached to that member-

ship” (Tajfel, 1981, p. 255). SCT extended this definition to include the idea that social identities are *depersonalized* representations of the self, entailing “a shift towards the perception of self as an interchangeable exemplar of some social category and away from the perception of self as a unique person” (Turner et al., 1987, p. 50). SIT, as articulated by Tajfel (1978) and Turner (1975, 1985), represents the convergence of two traditions in the study of intergroup attitudes and behavior—social categorization (as represented in the work by Doise [1978], Tajfel [1969], and Wilder [1986]) and social comparison (as exemplified by Lemaine [1974] and Vanneman and Pettigrew [1972]). The theoretical perspective rests on two basic premises:

1. Individuals organize their understanding of the social world on the basis of categorical distinctions that transform continuous variables into discrete classes; categorization has the effect of minimizing perceived differences *within* categories and accentuating intercategory differences.
2. Because individual persons are themselves members of some social categories and not others, social categorization carries with it implicit *ingroup–outgroup* (we–they) distinctions; because of the self-relevance of social categories, the ingroup–outgroup classification is a superimposed category distinction with affective and emotional significance.

These two premises provide a framework for conceptualizing any social situation in which a particular ingroup–outgroup categorization is made salient. In effect, the theory posits a basic *intergroup schema* with the following characteristic features: (1) assimilation within category boundaries and contrast between categories such that all members of the ingroup are perceived to be more similar to the self than members of the outgroup (the *intergroup accentuation* principle); (2) positive affect (trust, liking) selectively generalized to fellow ingroup members but not to outgroup members (the *ingroup favoritism* principle); and (3) intergroup social comparison associated with perceived negative interdependence between ingroup and outgroup (the *social competition* principle).

SIT in conjunction with SCT provides a single comprehensive theory of group behavior and the cognitive processes that underlie a

range of intergroup and group phenomena. The basic tenet of these theories is that group behaviors derive from cognitive representations of the self in terms of a shared social category membership, in which there is effectively no psychological separation between the self and the group as a whole. This phenomenon is referred to as *depersonalization of self-representation*, whereby the cognitive representation of the self shifts from *personal self* to *collective self* (Hogg & Abrams, 1988; Hogg & Turner 1987).

SIT articulates how cognitive representations of self and a relevant ingroup correspond when ingroup identification (social identity) is psychologically salient. When individuals categorize the self and view themselves as indistinguishable from the ingroup, they also view other ingroup members as interchangeable with one another. The representation of the ingroup is embodied in a “prototype,” defined by features shared by group members. Such prototypical features capture ingroup similarities and intergroup differences that distinguish the ingroup from comparison outgroups. Perceptions of the self and other ingroup members are then assimilated to this ingroup prototype. When a shared social identity is salient, ingroup members are perceived as similar to one another, and the ingroup as a whole is perceived to be a homogeneous unit (Doosje, Ellemers, & Spears 1995; Haslam, Oakes, Turner, & McGarty, 1996; Simon & Hamilton, 1994). The affective and behavioral consequences of social identity lead to intergroup situations characterized by preferential treatment of ingroup members, mutual distrust between ingroup and outgroup, and intergroup competition.

Culture and Meaning of Social Identity

Parallel to individualism and collectivism, SIT/SCT postulate a continuum anchored by personal (individuated) identity at one end and social (collective) identity at the other. The shift between personal and social identities is presumed to lie in universal cognitive processes associated with social categorization and category salience. Against this view of a single continuum, Brewer and Gardner (1996) postulated that there are three different levels of the “social self”—the *individual*, *relational*, and *collective*—as distinct self-representations with different structural properties, bases of self-evaluation, and motivational concerns (see also

Kashima & Hardie, 2000; Gabriel & Gardner, 1999; Sedikides & Brewer, 2001). The individual self is the representation of self as a unique person, differentiated from other individuals. The relational self is the self defined in terms of connections and role relationships with significant others (Aron, Aron, Tudor, & Nelson, 1991; Cross & Madson, 1997; Gilligan, 1982; Markus & Kitayama, 1991). The collective self is the social identity of SCT, defined in terms of prototypical properties shared among members of a common ingroup (Turner et al., 1987).

The relational and collective levels of self postulated by Brewer and Gardner (1996) represent two different forms of social identification (i.e., processes by which the individual self is extended to include others as integral to the self-concept). The critical distinction between these is that relational selves are *personalized*, incorporating dyadic relationships between the self and specific close others, and the extension of these relationships in the form of networks of interpersonal connections. By contrast, collective selves involve *depersonalized* connections with others by virtue of common membership in a symbolic group. Collective identities do not require interpersonal knowledge or coordination, but rely on shared symbols and cognitive representations of the group as a unit independent of personal relationships within the group.

Drawing on this distinction between relational and collective social selves, Yuki (2003) suggested that the predominant characteristics of group cognition and behavior may differ across certain cultural contexts. According to this framework, processes consistent with SIT and SCT are most applicable to intergroup situations involving people from Western cultures. The typical characteristics of group cognition and behavior for East Asians, however, may be qualitatively different from those of Westerners. Whereas people in Western cultures tend to emphasize the categorical distinctions between ingroups and outgroups, East

Asians may have a stronger tendency to think about groups as predominantly *relationship-based*. In group contexts, East Asians tend to perceive themselves as a “node” embedded within a network of shared relationship connections (i.e., family members, friends, colleagues, acquaintances, friends of friends, etc.) rather than within strict, bounded groups per se. Within this framework, the ingroup for East Asians is cognitively represented as a relatively stable and structured network of relationships among group members.

Whereas SIT implicates intergroup comparison as a key source of ingroup identification and cooperation, Yuki’s framework proposes that East Asian collectivism is based largely on the promotion of cooperative behaviors and maintenance of relational harmony *within* ingroups. It is important to note that this framework does not suggest that East Asians ignore the ingroup as a meaningful social unit, and research indeed suggests that they do impose boundaries between ingroups and outgroups (Gudykunst, 1988; Smith & Bond, 1999). However, East Asians tend not to depict their ingroups as depersonalized entities (as conceptualized in SIT), but as complex networks of interrelated individual members (Chang, Lee, & Koh, 1996; Hamaguchi, 1977; Ho, 1993; Hwang, 1999; King & Bond, 1985; Kim & Lee, 1994; Lebra, 1976; Munro, 1985). This type of group representation is consistent with research demonstrating that there are different bases for group entitativity and group attraction, with some groups emphasizing their categorical, depersonalized nature, and others emphasizing the structured relational networks and interpersonal bonds among members (Hamilton, Sherman, & Lickel, 1998; Prentice, Miller, & Lightdale, 1994; Seeley, Gardner, Pennington, & Gabriel, 2003).

A summary representation of the postulated differences between relational and collective bases of social identity is provided in the Table 12.1.

TABLE 12.1. Comparing Relational and Collective Social Identity

	Relational	Collective
Self-concept	Individuated/connected directly or indirectly with others	Depersonalized/defined in terms of prototypicality
Motivation	Reciprocity	Intergroup status/competition
Group representation	Interpersonal network	Depersonalized entity

Rather than thinking about groups as categories of depersonalized members, East Asians are especially concerned about maintaining a high level of knowledge about the complex relational structure within the ingroup. According to Yuki (2003), East Asian group members chronically perceive themselves to be personalized from and connected with other members, and they are aware of the exact location of the self within the group represented as a network. Furthermore, some theorists have suggested that it is this relational knowledge that allows East Asians to strategically promote self-interests within the complex relational structure in a group (Yamagishi, Jin, & Miller, 1998). Relational knowledge determines the expected behavior of individuals within the group and serves to maintain mutually beneficial relationships among group members (Aoki, 2001; Hwang, 1999; Nakane, 1970).

Experimental findings from a study by Yamagishi and Kosugi (1999) provide indirect evidence for this view. These researchers found that their Japanese participants who had high external locus of control and low generalized trust (characteristics typical in collectivistic societies) were in fact better at judging good and bad relationships among classmates than were participants who were high in internal locus of control and generalized trust.

Overall, then, the conceptualization of ingroups and group behavior in East Asia tends to place less emphasis on categorization, intergroup comparison, and depersonalization of the self, and places more emphasis on maintaining harmony within groups, being sensitive to the needs and feelings of others, and being aware of the relationship structure within the group (Yuki, 2003). In a collectivist society, where awareness of interdependence and status relationships is high, relational ties are the key to social identification with ingroups.

Two Bases of Social Identity

Although Yuki's (2003) theory was developed specifically in the context of comparisons between Western cultures (particularly Western Europe and the United States) and East Asian cultures (particularly Japan), we believe that the distinction between relationship-based and category-based social identities provides a useful framework for viewing cultural effects on social identity processes more broadly. In fact, many East Asian cultures other than Japan ap-

pear to emphasize relationship-based social identity, although specific forms do vary from culture to culture. Pye (2000) argues that Chinese social identities are based on particularistic relationships that radiate out from immediate family to extended kin to shared identities based on hometown or university attendance, whereas Japanese social bonds are more subjective and based on personal relationships of indebtedness and obligation (p. 126). Relationship-based social identity is also prevalent in Africa. For instance, Adams and Dzokoto (2003) suggest that social identity in West Africa is best characterized as "relational individualism," in that individuals make case-by-case decisions as to whether to trust others by taking into account the relational connections to them (Shaw, 2000). This ethos is very different from the depersonalized collective self of SIT. Many Africanists, in fact, have argued that larger, more depersonalized collective identities, such as ethnicity and nationality, are the product of social constructions that emerged only after European colonization (e.g., Nagel, 1994; Yeros, 1999).

Across all societies, individuals maintain close personal relationships, small-group interpersonal networks, and membership in large, symbolic groups (Brewer & Caporael, 2006; Caporael, 1997). But cultural systems rely more or less heavily on these different forms of social connection as the primary locus for defining the social self and exercising social control over individual behavior. It is primarily Western European and North American individualistic cultures that rely heavily on abstract, categorical group memberships in constructing social identities. Other cultures appear to rely more on relational networks to do so. Two theoretical perspectives can be brought to bear to help account for this broad cross-cultural variation of the basis of social identity.

According to Berry's (1979) ecological model of culture, cultural differences in social relationships emerge in part from socio-ecological factors such as geography, social structure, and mobility. Drawing on this model, Oishi (2005) has argued that social mobility plays an especially important role in determining salient aspects of self and ingroups. In a low-mobility society, group membership is generally ascribed and predetermined. People cannot escape from the group even if they find that their own attitudes, goals, and so on, are

not fully compatible with those of fellow group members. What they have to do is to maintain good relationships with others, by recognizing and accommodating individual differences in attitudes, goals, and so on, within the group. Thus, relationships rather than similarity or homogeneity define group boundaries.

By contrast, in a society where individuals move frequently, group memberships do not last as long as in a society where individuals live in the same community for a long period of time. To the extent that social aspects of the self (e.g., relationships, roles, group membership) change more frequently in a highly mobile society than they do in a nonmobile society, collective selves should be less consistent across time in the former society than in the latter. Instead, groups are formed around similarities and common interests, with symbols to demarcate group membership and coordinated action. Given the association between mobility and individualism (Triandis, 1995), this ecological model provides an explanation for why individualism is associated with depersonalized, symbolic collective identities, whereas less mobile, collectivistic societies are characterized by stable, relationship-based social identities.

A second, related, explanation for the observation that individualism is associated with category-based social identity comes from Brewer and Roccas (2001), who contend that the nature of collective selves is shaped and constrained by the relative importance placed on values of independence (individual autonomy) versus interdependence in relations between the self and others in a society. With emphasis on obligation, mutual interdependence, and responsibility to ingroup others in societies with relational collectivistic values, social identification with groups is a high-investment commitment. This means that the benefits of group inclusion are high, in that groups provide security and guaranteed mutual aid. Yet it also implies that the costs of inclusion are also high in terms of obligations and duties to fellow group members that demand time and resources. When intragroup obligations are strong and underwritten by group norms and sanctions, the benefits of group inclusion can best be met within relatively small, stable, and exclusive social units. Accordingly, in collectivist cultures, relationship-based ingroups are optimal.

Individualistic value orientations, with a strong emphasis on individual autonomy and

social mobility, have very different implications for the demands and level of investment associated with group memberships. At first glance, it may appear that individualistic values are incompatible with the very notion of collective social selves. To the contrary, we believe that individualism has very direct effects on the need for inclusion in larger social units, such that individual autonomy and collective identity with large, depersonalized groups are quite compatible. Because individualism gives greater weight to personal interests and preferences in resolving potentially conflicting demands of individual achievement and the welfare of others, obligations to groups and fellow group members are neither absolute nor highly reliable. Thus, the potential benefits of ingroup inclusion are diffused and probabilistic, and individuals need to be part of larger and more inclusive social units to reap the benefits of security and mutual aid associated with group membership. In effect, the attachment to large, depersonalized groups, such as nation, ethnicity, and religion, is a function of the loss of the tightly interdependent community associated with social mobility and individualism.

Cultural values and practices that embody implicit rules of social exchange, expectations of mutual obligation, and sources of social approval all shape where individuals invest their self-definition, affective attachments, and, most important, social identities. These cultural effects on which social identities matter in turn determine the role that social identification plays in interpersonal and intergroup behavior.

Bases of Ingroup Identity: Some Empirical Findings

The distinction between relationship-based and category-based social identities helps to make sense of some otherwise anomalous findings in the literature on the relationship between individualism–collectivism and self-concept. The simple assumption has been that the self-concepts of persons in individualistic cultures consist primarily of idiocentric traits and attributes, whereas members of collectivist cultures incorporate more social references, including allocentric, relational constructs and group memberships, in their salient self-representations (Triandis, 1989). But comparative research on the spontaneous self-concept of respondents in different cultures has not

consistently supported this simple relationship between culture and content of representations of the self. Some studies comparing self-descriptions of participants from individualistic and collectivist societies (including Kenya, Malaysia, India, Japan, China, and Korea), and individualistic societies (U.S., Britain, and Australia) have found support for the contention that collectivists generate a larger proportion of social identity references (Bochner, 1994; Dhawan, Rosemen, Naidu, Thapa, & Rettek, 1995; Kashima et al., 1995; Ma & Schoeneman, 1997; Ross, Xun, & Wilson, 2002; Trafimow, Triandis, & Goto, 1991; Triandis, McCusker, & Hui, 1990). On the other hand, some studies have found that U.S. respondents used an equal, or sometimes even greater, proportion of social descriptors in their spontaneous self-concepts than respondents from Japan, China, or Korea (Bond & Cheung, 1983; Cousins, 1989; Ip & Bond, 1995; Rhee, Uleman, Lee, & Roman, 1995).

The picture becomes a bit clearer when one looks more closely at different types of social identity responses in these studies. In general, participants from collectivist cultures generate more references to social relationships and role identities in their spontaneous self-descriptions, but respondents in individualistic cultures generate an equal or greater number of references to social group or social category memberships. Furthermore, in their meta-analysis of cross-cultural comparisons of individualism and collectivism, Oyserman et al. (2002) found that Americans score high on collectivism when measures include items tapping a "sense of group belonging" as an aspect of collectivist orientation.

In a particularly comprehensive cross-cultural test using sentence completion responses to the Twenty Statements Test (TST; Kuhn & McPartland, 1954) as a measure of salient self-concept, Watkins et al. (1998) obtained responses from a large number of university students from four different individualistic cultures (Australia, Canada, New Zealand, and whites in South Africa) and five collectivist cultures (China, Ethiopia, Philippines, Turkey, and blacks in South Africa). Self-descriptions were classified as idiocentric (e.g., personal qualities, traits, attitudes), allocentric (relational constructs: sociable, good friend, etc.), small-group memberships (e.g., family relationships), and large group memberships ("I am a student," "I am Chinese," etc.). The re-

sults indicated a great deal of variability across the nine cultures in the percentage of responses of each type. Overall, however, members of individualistic cultures and of collectivist cultures generated approximately the same proportion (65–70%) of idiocentric self-descriptions. What differed was not the total proportion of social self-descriptions but rather the *type* of social reference that appeared most frequently. On average, respondents from countries classified as collectivistic generated more responses categorized as *allocentric* or *small-group* memberships, whereas respondents from individualistic countries generated more references to *large-group* memberships.

In an experimental study, Brewer and Gardner (1996) found that the frequency of relational terms or references to large-group memberships in TST self-descriptions could be influenced by a priming manipulation that induced participants to think about either small-group relations or large collectives. When the meaning of *we* was contextualized to refer to interpersonal relationships, responses to the Who Am I? test included a larger proportion of relationship identities (e.g., "I am a daughter," "I am a good friend") compared to a control condition in which no *we* priming was given. On the other hand, when the *we* prime was presented in the context of a large collective group, responses to the TST included a larger proportion of category memberships (e.g., "I am an American," "I am a woman"). These experimental findings confirm that relational and collective responses to the TST are sensitive to the activation of different types of social identities.

Overall, then, findings from a variety of studies regarding the presence of social identifiers in spontaneous self-concept are consistent with the idea that cultures do not differ in *whether* social identities are important aspects of the self-concept but in *what type* of social identity is more salient.

In a more direct test of cultural differences in the meaning of ingroup social identities, Yuki (2003) conducted a comparative study between Japan and the United States on predictors of the strength of ingroup identity and loyalty. He asked both American and Japanese university students to report how they perceived two kinds of ingroups of different sizes—their nation and a small social group to which they belonged (e.g., club or activity group). One set of measures involved perceived relational connec-

tions with the groups, such as knowledge about individual differences and relationships among group members, and the sense of interconnectedness between the self and other group members. Another set of measures pertained to features of the ingroup as a social category, such as perceived intragroup homogeneity and status relative to outgroups. Yuki found that for Japanese students, ingroup identification and loyalty were determined solely by the relational factors, with no significant correlation with the categorical factors. In contrast, among American students, identity and loyalty were associated significantly with both the relational and the categorical factors. This pattern of findings is consistent with our model of cultural difference in the meaning and cognitive representation of social ingroups.

SOCIAL IDENTITY AND SOURCES OF SELF-WORTH

Understanding the bases on which individuals in different cultures define ingroups and social identities takes on added significance when one considers the relationship between social identity and psychological functioning. Cultural values and practices influence which social units have the most impact on members' self-representations and what qualities contribute most to positive psychological well-being (Deaux, 1993). One line of research on social identity effects investigates the extent to which individuals derive their sense of self-worth and well-being from their social group memberships or social relationships. In cultures where depersonalized, symbolic, or categorical group identities are most prominent, collective self-enhancement may be an important source of self-worth. In cultures where ingroups are defined primarily as relational networks, well-being and self-esteem may be more closely associated with enhancement of the quality of relationships and relationship partners. This hypothesis helps us integrate some divergent sets of findings from the cross-cultural literature.

In the United States, the self-enhancing function of group identity has been studied primarily in relation to the concept of "collective self-esteem" (Luhtanen & Crocker, 1992), which refers to individuals' evaluations of their social identities and the role of their group memberships in contributing to their personal self-worth. Measurement of collective self-esteem

has identified four related but distinct components (subscales)—*identity importance* (how important group memberships are to the individuals' self-concept), *member esteem* (individuals' assessment of their value as group members), *private esteem* (individuals' personal evaluation of their membership groups), and *public esteem* (individuals' assessment of how others evaluate their membership groups). In initial studies of the collective self-esteem scale, each of these components was found to correlate to some degree with personal self-esteem (Luhtanen & Crocker, 1992). However, consistent with Yuki's (2003) findings regarding the importance of intergroup comparison and status on ingroup identity and loyalty among white college students in the United States, public collective self-esteem is a significant contributor to personal self-esteem (Crocker, Luhtanen, Blaine, & Broadnax, 1994; Luhtanen & Crocker, 1992). Even among low-status minority groups, strength of ethnic identification and collective self-esteem is positively related to measures of self-worth and well-being (Branch, Tayal, & Triplett, 2000; Crocker et al., 1994; Verkuyten & Lay, 1998), suggesting that group identification serves to buffer self-worth from the effects of social discrimination (Branscombe, Schmitt, & Harvey, 1999).

By contrast, evidence suggests that for East Asians, collective ingroup enhancement is not a significant basis of personal self-esteem (Heine, 2003). This seems particularly true when the target ingroup is a large categorical collective, such as national or university identities. Hewstone and Ward (1985), for instance, obtained evidence of group-effacing attributional biases among Chinese in reference to their ethnic group. Bond and Hewstone (1988) found that British high school students in Hong Kong had more positive images of the ingroup than did Chinese students. Similarly, Rose's (1985) cross-national study found that Americans had more positive views of their country than did Japanese, and Heine and Lehman (1997) found that Japanese students' ratings of their own universities were worse than ratings by students from rival universities. Finally, Snibbe, Kitayama, Markus, and Suzuki (2003) found significantly less ingroup favoritism among Japanese football fans compared with their American counterparts. In contrast to American students, who clearly showed intergroup bias, their Japanese counterparts, although equally identified with their university and the

sports team, did not show any evidence of intergroup bias.

Importantly, although East Asians rarely enhance their collective self-esteem, they do exhibit significant relationship-enhancing bias, as indicated by the difference between evaluations of their own relationships and of “average” relationships (Endo, Heine, & Lehman, 2000; see also Sedikides, Gaertner, & Toguchi, 2003). Even the absence of self-enhancement and the emphasis on self-critical attitudes have been interpreted as being designed to maintain good relationships with others (Heine & Lehman, 1997; Kitayama, Markus, Matsumoto, & Norasakkunkit, 1997). The motivational significance of relationship enhancement for Asians is further suggested by the finding that relationship harmony is more strongly associated with subjective well-being in Hong Kong than in the United States (Kwan, Bond, & Singelis, 1997; Kurman & Sriram, 1997).

CONSEQUENCES OF SOCIAL IDENTITY FOR INTRAGROUP AND INTERGROUP PROCESSES

Considering social identity from a cultural perspective has implications for understanding group-level phenomena, as well as individual self-concepts. Our general point is that different bases for social identity have different implications for how social identity regulates intragroup and intergroup processes and outcomes (see Hong, Wan, No, & Chiu, Chapter 13, this volume). By considering how culture shapes the meaning of ingroups, we can shed some light on apparent anomalies in the cross-cultural literature on trust and intergroup behavior.

Intragroup Processes: Trust and Cooperation

In the social science literature, there has been a recent resurgence of interest in trust as a central psychological construct (Buchan, Croson, & Dawes, 2002; Foddy, Platow, & Yamagishi, 2003; Kramer, 1999; Yamagishi, Foddy, Makimura, Matsuda, & Platow, 2003). For our purposes, “trust” is defined as an expectation of beneficent treatment from others in uncertain or risky situations (Foddy et al., 2003). In general, the concept of trust reflects a belief that others will act in a way that will benefit (or not harm) oneself, *before* one knows the outcome of other’s behaviors (Dasgupta, 1988).

Trust is typically called for in situations where another person has the potential to gain at one’s expense but can choose *not* to do so (Yamagishi & Yamagishi, 1994).

Of particular interest is the role of trust in contexts and institutions where participants must decide whether to rely on others without personal knowledge about them or history of an interpersonal relationship (Cook, 2001; Foddy et al., 2003; Kramer, 1999; Ostrom, 1998; Tyler, 2001; Yamagishi et al., 2003; Yamagishi & Yamagishi, 1994). Although it is generally difficult to establish trust in a person whom one does not know personally, such interpersonal trust is essential for the creation and maintenance of many forms of economic exchange, organizations, and social and political institutions.

Macy and Skvoretz (1998) state that the “earliest trust rule is based on social distance—trust neighbors, but not outsiders” (p. 651). Individuals may trust others if they know (or believe) that they and others are directly or indirectly connected through mutual friendships or acquaintances (Coleman, 1990). A shared network of interpersonal relationships provides a mechanism for extending *personalized* trust to unknown others who are part of the social network. On the other hand, shared category membership (a common ingroup) may be a basis for *depersonalized* trust (Brewer, 1981; Buchan et al., 2002; Macy & Skvoretz, 1998; Yamagishi & Kiyonari, 2000). As a consequence of shifting psychologically from the personal to the collective level of identity, one may be less likely to distinguish the interests of other ingroup members from those of oneself, leading to increasing trust toward fellow ingroup members whether personally known or not. Research on the consequences of social identity has demonstrated that mere shared ingroup membership is sufficient to engender trust and cooperation. When a shared social categorization has been made salient, individuals are more likely to trust that an allocator will share resources fairly (Foddy et al., 2003), to cooperate to conserve group resources (e.g., Brewer & Kramer, 1986; DeCremer & van Vugt, 1999), and to contribute to a public good without knowing whether others are also contributing their share (Wit & Kerr, 2002).

But recent research shows that this tendency to trust ingroup members is qualified by cultural differences. Interestingly, evidence indicates that this ingroup bias in trust is actually

larger for those who have an individualistic cultural orientation or people from individualistic cultures, rather than for collectivists and people from collectivistic cultures. Buchan et al. (2002), for instance, tested individuals' willingness to trust others in an investment game involving an indirect exchange situation. They found that participants with an individualistic cultural orientation increased their levels of trust in unknown others (in terms of amount of monetary investment) when an arbitrary category boundary was introduced to provide exchange participants with a common social group identity. Participants with a collectivist orientation, however, did not alter their level of trust, whether a category identity had been made salient or not. Using a similar procedure in a subsequent study, Buchan, Croson, and Johnson (2003) found that U.S. participants showed a clear ingroup bias in trust, whereas Chinese participants did not show such a tendency at all. Likewise, Yamagishi et al. (2003) found that sharing group membership (e.g., same country, same university) was sufficient to generate higher trust in ingroup members for Australians, but not for Japanese.

These counterintuitive findings regarding the relationship between collectivist cultural values and intragroup trust can be explained (at least in part) by recognizing the difference between relationship-based and category-based ingroups. As we have been arguing, East Asians' group behaviors are predominantly intragroup- and relationship-based. Groups are constructed so that members can monitor each other's behavior, and high visibility of individual members may serve as a mechanism for inhibiting potential freeriding (Miller & Kanazawa, 2000; Yamagishi et al., 1998). In fact, Yamagishi's cross-cultural experiments showed that Japanese became less cooperative and less trusting toward the ingroup when there was no system of ingroup monitoring and sanctioning, whereas Americans did not change their level of cooperation and trust as a function of the presence or absence of a monitoring and sanctioning system (Yamagishi, 1988a, 1988b). In contrast to a mechanism of cooperation based on depersonalized shared group membership, relationship-based trust and cooperation are dependent on interpersonal connections and reciprocal obligations (Yamagishi et al., 1998).

This evidence of cultural differences led Yuki, Maddux, Brewer, and Takemura (2005) to speculate that differences in the meaning of ingroups (and corresponding social identities)

are associated with different bases of ingroup trust and cooperation across cultures. More specifically, they hypothesized that Americans' group behavior is based on the categorical distinctions between ingroups and outgroups, and depersonalized trust is based on knowledge that self and other share membership in a bounded social category. By contrast, if Japanese group behavior is driven more by the importance of relationship networks, trust should be highest toward individuals who are presumed to share a direct or indirect network of relationships with the self, regardless of category boundaries. Shared ingroup membership may provide one basis for inferring relational connections to an unknown other, but potential network ties across category boundaries should be equally likely to elicit trust. In other words, it was predicted that if an unknown outgroup member shares an indirect interpersonal connection with the self (through a personal acquaintance), this cross-group relationship link should generate trust for an outgroup member in Japan but not in the United States.

Results from two experiments supported the hypothesis that the bases of ingroup trust differ across cultures. Across both studies, Americans tended to trust strangers based on the categorical differentiation between those who share the same group memberships and those who do not, and having an acquaintance in the outgroup had no effect on levels of trust. This pattern demonstrates that trust is depersonalized for Americans, consistent with the social identity model in which group behavior and cognition are based primarily on categorical differentiation between ingroup and outgroups. In contrast, trust for Japanese participants depended more on the likelihood that targets shared direct or indirect relationship links. In particular, the presence of a potential cross-group relationship had a strong effect on outgroup trust for Japanese. The results from our Japanese samples are congruent with the hypothesis that Japanese group behavior and cognition are relationship-based (Yuki, 2003), with Japanese trusting those who most likely shared direct and indirect interpersonal relationships, as exemplified by the high levels of trust toward both ingroup members and outgroup members with potential relationship connections. Overall, then, these experiments on trust support our general theoretical framework that representations of ingroups and bases of social identity differ across cultural context.

Intergroup Processes: Ingroup–Outgroup Discrimination

In addition to intragroup behavior, the cultural basis of ingroup identity has important implications for *intergroup* relations. Ingroup–outgroup discrimination refers to differences in behavior directed toward members of ingroups in comparison to outgroup members, particularly behaviors that benefit ingroup members and/or disadvantage outgroupers. The question here is whether ingroups based on relational interdependence and ingroups based on symbolic categories have similar effects on attitudes and behavior toward outgroup members.

In the literature on individualism–collectivism, the claim has been made that members of collectivist cultures make sharper distinctions between ingroup behavior and outgroup behavior than do members of individualistic cultures (Triandis, 1995). As Iyengar, Lepper, and Ross (1999) put it, “As the self–other boundary becomes less distinct, the distinction between ingroup members and outgroups members assumes greater significance. . . . Assimilating ingroup members to self may lead individuals to contrast ingroup and outgroup members more sharply, making them relatively more susceptible to different cognitive, perceptual, and motivational biases” (p. 279).

A number of comparative studies have supported this idea that collectivist values are associated with greater ingroup–outgroup differentiation. For example, Leung (1988) found that in responses to conflict scenarios between two disputants, Hong Kong Chinese college students were less likely to pursue a conflict with an ingroup disputant (close friends) and more likely to pursue a conflict with an outgroup disputant (strangers) than were American students. Similarly, studies on distributive justice have shown that people from collectivist cultures apply different reward allocation norms to ingroup and outgroup. Leung and Bond (1984), for instance, found that Chinese participants shared the rewards more equally with the friends, but with an outgroup stranger they adhered to the equity norm more closely than did the Americans. Likewise, Mahler, Greenberg, and Hayashi (1981) asked students in Japan and in the United States how rewards should be divided in a set of stories describing two workers. American participants tended to favor an equity allocation based on relative contribution of the two workers, regardless of whether the workers were friends. Japanese

participants, on the other hand, favored an equality allocation when the two workers were described as strongly connected, though their allocation preferences were the same as Americans when the story implied that the two workers were not strongly connected.

In contrast to these findings that indicate that East Asians discriminate between ingroup and outgroup situations more than Americans do, the implications from research by Yuki (2003), cited previously, indicate that intergroup comparisons between social categories are more important to Americans than to Japanese. In the European and American literature on social identity, the role of category salience in ingroup–outgroup discrimination has been well documented in experimental research using the minimal intergroup paradigm (Tajfel, 1970; Tajfel, Billig, Bundy, & Flament, 1971; Brewer, 1979; Turner, 1981; Diehl, 1990).

“Minimal groups” are depersonalized social categories based on arbitrary category distinctions between ingroup and outgroup. Indeed, there is evidence to suggest that ingroup bias based on such categorical distinctions may in fact be more pronounced in Western than in Asian cultures. Wetherell (1982) conducted a study to test cross-cultural robustness of ingroup favoritism in minimal groups in New Zealand. She found that children with a Polynesian background showed weaker ingroup bias than did those with European background, and they instead attempted to benefit both ingroup and outgroup members. In the previously cited study by Buchan et al. (2003), half of the participants played the role of “responders,” who were asked to decide whether they should return a portion of the money received (with trust) from the “senders,” who were either in the (minimal) ingroup or outgroup. The results showed that American participants exhibited significant ingroup bias, returning a greater amount of money to the ingroup than to outgroup senders, whereas Chinese showed the opposite tendency. Furthermore, this cultural difference was mediated by cultural orientation of individualism–collectivism (i.e., the effect of culture disappeared when individual difference in individualism–collectivism was statistically controlled), with individualists showing more ingroup bias than collectivists within both countries. Other evidence suggests that East Asians do not readily engage in outgroup discrimination in minimal group settings when discrimination does not indirectly benefit the self (Yamagishi, Jin, & Kiyonari, 1999).

The apparent contradiction in conclusions drawn in the literature about the relative ingroup–outgroup discrimination of collectivistic and individualistic societies can be resolved when one looks more closely at how ingroups are defined in different studies and what types of intergroup discrimination are being assessed. In the typical minimal group studies, ingroups are defined as genuinely categorical, in the sense that they are determined based on arbitrary bases, such as by lottery, dot estimation tendency (overestimator vs. underestimator), and artistic preference, and, more importantly, there is no substantial interdependence among members. However, as discussed earlier, ingroups for collectivists are more relationship-based networks, where interdependence within ingroup is of crucial importance. In contrast to the positive intergroup distinctiveness principle governing intergroup behaviors, as depicted by SIT, East Asian intergroup behaviors can be characterized as strategies that maximize one's own personal interest by maintaining mutually beneficial relationships with fellow ingroup members (Hamaguchi, 1977; Yamagishi et al., 1998).

In East Asian cultures, the obligation to cooperate is applicable primarily in interaction with friends rather than with strangers. In a recent experiment on the effects of cultural cues on social behavior, subsequent to being primed with Chinese (vs. American or culture-neutral) symbols, Chinese American biculturals were more cooperative when they played the prisoner's dilemma game with their friends. However, culture priming did not affect these biculturals' cooperative or competitive choices when they played the game with strangers (Wong & Hong, 2005).

Congruent with this reasoning, a series of studies by Yamagishi and colleagues (Jin, Yamagishi, & Kiyonari, 1996; Karp, Jin, Yamagishi, & Shinotsuka, 1993) showed that Japanese engage in ingroup favoritism in a minimal group situation when an apparent cue of intragroup interdependence is provided. In a condition where participants were each told that he or she was the only person within the ingroup who was given the reward allocation task, they did not show ingroup favoritism. They did, however, favor the ingroup when it was emphasized clearly that everyone in the experiment was performing the reward allocation task, which supposedly made them think about interdependence (and reciprocity) within their group. These findings are consistent with Bene-

dict's (1946) suggestion that the source of Japanese ingroup loyalty is the maintenance of strictly reciprocal relationships with fellow ingroup members. In contrast, participants in minimal group experiments in North America and Australia show significant ingroup discrimination even when reciprocal interdependence within groups has been eliminated (e.g., Perreault & Bourhis, 1998; Platow, McClintock, & Liebrand, 1990), suggesting that ingroup favoritism in these cultures is based on desire to benefit the ingroup as a whole rather than on expectation of reciprocal favors.

SUMMARY AND CONCLUSIONS

Our thesis throughout this chapter has been based on the idea that all cultures rely on social identification and ingroup loyalty, trust, and cooperation as an essential mechanism of social coordination and social control. The nature of social identities, however, is embedded in cultural values and practices, with the consequence that ingroup boundaries and ingroup–outgroup distinctions may be culture-specific. Although the nature of these differences in defining ingroups and social identity may vary along a number of dimensions, we have emphasized one important distinction, namely, the difference between social identities based on networks of interpersonal relationships and social identities based on shared membership in depersonalized collectives. We have reviewed research showing that this distinction is consistent with findings from cross-cultural comparisons of bases of self-esteem, intragroup trust, and intergroup discrimination. A great deal of the empirical research conducted in this area involves comparison between individualistic cultures, represented by the United States, Europe, and Australia, and collectivistic cultures, represented by East Asia. We are convinced, however, that this distinction can be used more broadly in future research on the role of culture in shaping and defining social identity and its consequences for individual, group, and intergroup processes.

CHAPTER 13

Multicultural Identities

YING-YI HONG
CHING WAN
SUN NO
CHI-YUE CHIU

The new millennium has started off in the direction of increased global connectivity and intercultural migration. According to the United Nations' 2002 report, at least 185 million people worldwide currently reside outside the country of their birth, and the number of immigrants has more than doubled since 1975, excluding tourism or other kinds of short-term entries. In general, developed countries received more migrants from undeveloped countries than the other way round. As a result, one of every 10 persons living in the more developed regions is a migrant. Although the United States and Germany are the two countries with the largest number of migrants, many other countries around the globe have comparably large immigrant populations as well. For example, more than 17% of the Canadian population and more than 21% of the Australian population are foreign born. In addition to migration, rapid growth in international travel and telecommunication has increased people's exposure to foreign cultures.

Critical analyses have effectively dispelled the early naive enthusiasm that the world is becoming a global village and that all regional

differences will be resolved through multilateral cultural hegemony (cf. Parameswaran, 2002; van Strien, 1997). In fact, despite the rhetoric of the global village, to many people living in multicultural societies, increased intercultural connectivity has heated up the fields in which the meanings of "the self" are contested. What does it mean to be a multicultural being? What does it mean to have a multicultural self? Such questions pertain to the nature of the multicultural mind and multicultural identities, and deserve serious attention from cultural psychologists. Our primary goal in this chapter is to draw attention to these important questions and to set up a tentative agenda for further discussion on these topics.

CONCEPTUAL DISTINCTIONS

Cultural Identity and Collective Identity

Before we start, it is worth discussing our definition of "multicultural identities" and how it is related to other types of self-representations. Brewer and Gardner (1996; see also Sedikides & Brewer, 2001) have delineated three ways to

represent the self, namely, the individual self (which is characterized by an individual's personal attributes), the relational self (which is characterized by personal relationships with significant others), and the collective self (which is characterized by memberships in social groups or categories). These three self-representations allow people to define the self in three ways—individual (personal) identity, relational (social) identity, and collective identity. We add another identity, cultural identity, by which we refer to self-definition with reference to a *knowledge tradition* (Barth, 2002), or a collection of ideas and practices shared or widely distributed in a delineated population.¹

On the surface, the construct of cultural identity may seem redundant with that of collective identity. However, this would be the case only when we equate a knowledge tradition (or culture) with a designated group, a practice with which many psychologists and anthropologists have taken issue (Appadurai, 1996; Friedman, 1994). Treating culture as a group is defensible only when a particular knowledge tradition is completely shared in the designated group. To be sure, there are cases where a particular knowledge tradition is widely distributed in a collective. However, even the most widely distributed knowledge tradition is seldom shared completely among all members of a group. For example, Christianity is widely distributed among Norwegians. About 90% of Norwegians are Christians, but a sizable percentage (10%) of them are not. Therefore, the Norwegian collective identity does not overlap completely with a Christian identity. Conversely, there are also instances in which people who identify with a particular knowledge tradition are geographically dispersed and do not belong to a well-defined collective (e.g., environmentalists around the world).

Furthermore, a collective identity may be conferred on people even when they do not necessarily identify with the knowledge tradition widely shared in the group. This is the case particularly for ascribed collective identities or identities conferred on an individual without the individual's prior consent (e.g., racial identity, gender identity, or the religious identity of Catholic babies who were baptized at birth). In short, collective identity and cultural identity are distinct constructs.

That said, we must acknowledge that although cultural identity and collective identity

are distinct constructs, cultural *identification* and collective *identification* are intimately related. Level of identification refers to the degree to which one forms a unit relation between the self and the pertinent identity. Individuals who have strong identification with a knowledge tradition believe that this cultural identity is an integral part of their self-definition. Conversely, individuals who have weak identification with a knowledge tradition view this cultural identity as being tangential to their self-definition. Similarly, identification with a collective refers to the extent to which group membership of the collective is central to a person's self-definition.

When individuals (e.g., Chinese) identify strongly with a widely believed knowledge tradition (e.g., Confucianism) to define a collective (e.g., ethnic Chinese), they may also identify strongly with the collective. Likewise, when identification with a collective is strong, identification with the knowledge tradition widely believed to characterize the collective may be strong too (Jetten, Postmes, & McAuliffe, 2002; McAuliffe, Jetten, Hornsey, & Hogg, 2003).

Multicultural Mind and Multicultural Self

Cultural learning directly through personal experiences with the practices in a culture, or indirectly through observations of how the knowledge tradition is institutionalized in a society or implemented in practices, is the process whereby a knowledge tradition is acquired. A knowledge tradition available to an individual increases in cognitive accessibility as it is repeatedly called out and applied to understand one's experiences and to coordinate social actions. However, it would be a mistake to assume that individuals who possess knowledge of a particular cultural tradition will necessarily identify with it (Jetten et al., 2002). We emphasize that learning and acquiring a certain knowledge tradition does not entail identification with it. Experiences of short-term cultural travelers provide a good illustration of this point. Tourists, international students, or expatriate workers may be able to acquire the knowledge traditions in a foreign society and apply the newly acquired knowledge to guide their practices in the foreign land, without identifying with these knowledge traditions (Chiu & Chen, 2004).

By extension, individuals who have been exposed extensively to two (or more) knowledge traditions may have developed some degree of fluency in both. The increased frequency and intensity of intercultural contacts described at the beginning of this chapter has greatly facilitated multicultural learning. Admittedly, the acquisition of a knowledge tradition that is radically different from the one that is most familiar may initially create a “shocking” experience (Ward, Bochner, & Furnham, 2001). However, when individuals have acquired a knowledge tradition that is sufficiently different from their native one, they may choose to apply the native or new knowledge tradition in a given concrete situation, cognitively place them in juxtaposition, and attempt to integrate the knowledge from different cultural sources to foster a creative synthesis (Chiu & Hong, 2005). In this sense, the meeting of more than one knowledge tradition in a person can increase flexibility in cognitive and behavioral responding, and bring forth a stream of cultural innovations and creativity.

Individuals who are fluent in more than one cultural tradition can identify with one, all, or some cultural traditions. The issue of managing dual or multiple cultural identities does not emerge until bicultural or multicultural individuals are confronted with the task of defining the self with reference to certain knowledge tradition(s). We illustrate our arguments with bicultural identities, assuming that the same arguments apply equally well to multicultural identities. When bicultural individuals manage and negotiate their dual cultural identities, they may need to consider the affective, social, and political implications of the identity options available to them. This may be accompanied by feelings of confusion and ambivalence, as well as intrapsychic conflicts, particularly when the issue of divided allegiance is made salient, such as when new immigrants in some countries are expected to assimilate into the mainstream culture. Some bicultural individuals may construct an integral bicultural identity by synthesizing their dual identities. Such creative synthesis has been a topic of focal attention in cultural psychology. There is also an extant literature on the implications of various multiple-identities management strategies for psychological adjustment and well-being.

Making a distinction between multicultural knowledge (mind) and multicultural identification (self) also allows us to discuss the possible

interactions between these two constructs. For example, given that knowledge tradition is the object of cultural identification, it is inconceivable that a person would identify with a culture without having at least some vague ideas of what constitutes the culture’s knowledge tradition. In some situations, individuals may express and affirm their cultural identity by applying the pertinent cultural knowledge, although the application of cultural knowledge does not always entail cultural identification.

The distinction between acquiring cultural knowledge and cultural identification is therefore a theoretically important one. This distinction has offered us a refreshing perspective to reorganize the rapidly expanding literature on multicultural mind and multicultural self. To exploit the theoretical utility of this distinction, we have organized this chapter into four major sections: We (1) describe the psychological principles that underlie application of multicultural knowledge, (2) review the psychological processes involved in the management and expression of multicultural identities, (3) discuss the possible interactions of multicultural knowledge and multicultural identities, and finally (4) situate the microscopic psychological processes reviewed thus far in the global, socio-political contexts where the dynamic interactions of the multicultural mind and the multicultural self unfold *in vivo*.

In summary, by bringing a sharper focus to the seemingly blurry distinction between the multicultural mind and the multicultural self, we seek to shed some light on the dynamic processes whereby multicultural individuals choose between different cultural lenses to construct the reality, depending on the changing needs of the moment. We also strive to illuminate how multicultural individuals construct a self-identity that fits their experiences in an evolving multicultural environment.

MANAGEMENT AND APPLICATION OF BICULTURAL KNOWLEDGE

When individuals become experts in more than one culture, they may switch cultural frames in response to cues of changing cultural demands in the environment. Specifically, their social information processing is channeled through the lenses of more than one culture, and their interpretive biases could be pushed in the direction of one or the other culture by the presence of

cultural cues in the immediate environment, a process we call “cultural frame switching.” Such dynamic and flexible application of cultural knowledge results in adaptive responses to the shifting bicultural milieus. In this section, we introduce the basic cognitive principles that mediate cultural frame switching, and discuss its implications for adaptive and competent intercultural behaviors.

Principles of Knowledge Activation

The term “culture” is used here to designate a coalescence of loosely organized knowledge (or learned routines) that is produced, distributed, and reproduced among a collection of interconnected individuals. To the extent that culture consists of a network of distributed knowledge, application of cultural knowledge should follow the basic principles that govern knowledge activation in specific situations: the principles of availability, accessibility, and applicability (Higgins, 1996; Wyer & Srull, 1986).

Availability of Bicultural Knowledge

Some knowledge items are more widely distributed in one culture than in others. Individuals must be aware of the relative distribution of knowledge across cultures before they can apply knowledge discriminatively and appropriately in different cultural contexts.

Extensive experiences with several different cultures may increase people’s awareness of the uneven distribution of various knowledge items in these cultures. There is some evidence for the idea that extensive bicultural experiences produce calibrated representations of the second culture. Although both Hong Kong and New York City are cosmopolitan cities, Hong Kong people arguably have more exposure to New York culture than do New Yorkers to Hong Kong culture. Given such asymmetry in the direction of cultural contacts, Lee (2002) found that Hong Kong undergraduates are more accurate in estimating the distribution of knowledge (e.g., general knowledge about flowers and landmarks) among New York undergraduates than are New York undergraduates in estimating the distribution of knowledge among Hong Kong undergraduates.

Other researchers have obtained similar findings in the estimations of subjective psychological knowledge. American undergradu-

ates are *slightly* more proud of their personal history of fulfilling personal aspirations (promotion pride) than of their personal success in meeting parental expectations (prevention pride; see Higgins et al., 2001, for discussions of these constructs). American undergraduates tend to be very accurate when they estimate the relative strength of promotion and prevention pride in American college student culture. Chinese undergraduates in Beijing have relatively limited experiences with American culture. When asked to estimate the relative strength of promotion pride and prevention pride among American college students, they overestimated the difference of American students’ endorsement of promotion pride and prevention pride by three times. By comparison, Hong Kong undergraduates have more exposure to American culture than do students in Beijing. Although Hong Kong undergraduates also overestimated the difference of American students’ endorsement of promotion pride and prevention pride, the magnitude of overestimation was much smaller (Ip, Chen, & Chiu, 2003). In short, with frequent contacts with a second culture, refined cultural knowledge about that culture is acquired. Availability of such knowledge leads to sensitivity to the distribution of different knowledge items in this culture.

Chronic Accessibility

Chronic accessibility of a knowledge item is a product of frequent use of that item (Higgins, 1996). Knowledge items that are frequently used in a cultural group are usually widely shared (Lau, Chiu, & Lee, 2001; Lau, Lee, & Chiu, 2004; Sechrist & Stangor, 2001), frequently reproduced in communication (Lyons & Kashima, 2001), widely represented in external or public carriers of culture (Menon & Morris, 2001), and cognitively accessible to members of the group (Hong, Morris, Chiu, & Benet-Martinez, 2000).

For example, in Asian cultures, group agency and aspects of the interdependent self are relatively well represented in commercial advertisements (Han & Shavitt, 1994; Kim & Markus, 1999), newspaper articles (Menon, Morris, Chiu, & Hong, 1999) and the languages (Kashima & Kashima, 1998). By contrast, in Western cultures, direct personal agency and aspects of the independent self are relatively well represented in these media. In addition, when asked to describe themselves,

Asians spontaneously mention more interdependent or group-related self-statements, and fewer independent self-statements than do Westerners, indicating that the interdependent or group-related self is more chronically accessible to Asians than to Westerners (Rhee, Uleman, Lee, & Roman, 1995; Wang, 2001). As such, cultures may differ in the chronic accessibility of ideas and practices.

Temporary Accessibility

Temporary accessibility refers to the heightened activation of a representation evoked by cues in the immediate context, which may remind individuals of an idea that is not chronically accessible. For example, although among American undergraduates the independent self has high chronic accessibility, American undergraduates mention more group attributes and fewer personal attributes when their collective self (“we”) is primed than when their individual self (“I”) is primed. This finding indicates that both individual and collective self-construals are available to some American undergraduates, and contextual priming calls out one or the other kind of self-construals (Gardner, Gabriel, & Lee, 1999; Trafimow, Triandis, & Goto, 1991). Similar findings have been obtained among Chinese students (Trafimow, Silverman, Fan, & Law, 1997; Gardner et al., 1999).

The principle of temporary accessibility may explain the phenomenon of cultural frame switching that many biculturals have experienced. Some individuals who have become enmeshed in more than one culture navigate situations in the second culture as experts. These biculturals may switch their mode of interpretation: In one situation everything is filtered through one cultural lens; in the next, through another one. Hong and her associates (Hong, Chiu, & Kung, 1997; Hong et al., 2000; Hong, Benet-Martinez, Chiu, & Morris, 2003) proposed that this occurs through spontaneous activation of cultural frames, which are interconnected knowledge structures, in response to cues of the cultural requirements of a situation. In one experiment that tested this idea, Chinese American biculturals (Hong Kong Chinese, Chinese Americans) were primed with either Chinese cultural icons (e.g., the Chinese dragon) or American cultural icons (e.g., Mickey Mouse). When primed with Chinese (vs. American) cultural icons, these biculturals

were more inclined to use a group agency model to interpret an ambiguous event; they made more group attributions and fewer individual attributions. Analogous culture priming effects have been found on spontaneous self-construal (Ross, Xun, & Wilson, 2002) and cooperative behaviors (Wong & Hong, 2005). In addition, the culture priming effect has also been replicated in studies that used different bicultural samples (Chinese Canadians, Dutch Greek bicultural children), and a variety of cultural primes (e.g., language, experimenter’s cultural identity; Ross et al., 2002; Verkuyten & Pouliasi, 2002).

Applicability of Cultural Knowledge

Cultural frame switching is not a knee-jerk response to situational cues. The evoked cultural frame is appraised for its applicability to the judgment context before it is applied; an accessible cultural idea does not impact judgments or behaviors unless it is applicable to the task at hand. As noted, Chinese-American biculturals would more likely apply a group (vs. individual) agency perspective to interpret a stimulus event when primed with Chinese cultural icons than when they are primed with American cultural icons. However, this occurs only when the group (vs. individual) agency perspective is applicable in the judgment context, such as when the tension between group agency and individual agency is highlighted (Hong et al., 2003).

Similarly, in Chinese cultural contexts, a cooperative (vs. competitive) script is applicable only in interaction with friends, not in interactions with strangers. Thus, subsequent to being primed with Chinese (vs. American or culture-neutral) primes, Chinese American biculturals are more cooperative when they play the prisoner’s dilemma game with their friends. However, culture priming does not impact these biculturals’ cooperative or competitive choices when they play the game with strangers (Wong & Hong, 2005).

Summary

Culture, like other knowledge, impacts judgments and behaviors when it is activated. Activation of cultural knowledge follows the general principles of availability, chronic accessibility, temporary accessibility, and applicability. As the foregoing analysis illustrates, re-

trieval of a specific cultural knowledge item is a probabilistic (as opposed to deterministic) process contingent upon the individual's chronic cultural experiences, the unfolding cultural milieu, and the situation-appropriateness of cultural knowledge. Thus, culture does not rigidly determine human behaviors. Instead, like other knowledge, culture is a cognitive resource for grasping experiences and pursuing life goals.

Bicultural Knowledge and Cultural Competence

Individuals with bicultural knowledge have more than one set of cultural tools to interpret the world (cf. DiMaggio, 1997; Shore, 1996). These tools may foster competent behaviors in at least three ways.

First, when people generate creative exemplars in a conceptual domain (e.g., animals on the planet Mars), even their most creative exemplars resemble the highly accessible exemplars in a related domain (e.g., animals on Earth, with eyes and legs). Apparently, a major constraint on creative conceptual expansion is the influence of the highly accessible exemplars (T. Ward, Patterson, Sifonis, Dodds, & Saunders, 2002). Normative, conventional views and ideas in a culture are frequently used to interpret and understand the world. If a cultural lens is used frequently enough to make sense of the environment, it becomes a learned routine, and a part of "routinized" culture (Ng & Bradac, 1993). Thus, although culture provides conventional tools for sense making and problem solving, it also impedes creativity (T. Ward et al., 2002).

If the categorical accessibility norms in a culture result from chronic cultural experiences, bicultural experiences may help to foster creative expansion of ideas. To elaborate, Idea A may have high categorical accessibility in Culture I and low categorical accessibility in Culture II. Conversely, Idea B may have high categorical accessibility in Culture II and low categorical accessibility in Culture I. An individual who has extensive experiences in Cultures I and II may be able to retrieve Ideas A and B spontaneously, place the two ideas in juxtaposition and through creative insights integrate the two ideas into a novel idea. This process, often referred to as "novel conceptual combination," has been shown to have beneficial effects on creative conceptual expansion (Hampton, 1997; Simonton, 1997, 2000; W.

Wan & Chiu, 2002). Indeed, many examples of creative conceptual expansion in daily life result from integrating indigenous cultural exemplars from diverse cultures. For example, furnishing a New York apartment with traditional Ming Dynasty furniture may give a creative postmodern feel to this home. Consistent with this idea, we found in a recent study that among European American university students, those who have more experiences with other cultures have a greater tendency to sample ideas from other cultures (Middle Eastern and Far Eastern cultures) and integrate them in a creative conceptual expansion task (Leung, Chiu, & Hong, 2003).

Second, in intercultural communication, bicultural experiences allow individuals to discover, adjust, and integrate new attitudes and values from the second culture (Casmir, 1992). As such, knowledge of other cultures may help to establish the common ground in intercultural interactions, such as international business negotiation or management of culturally heterogeneous work teams (e.g., Earley, 2002; Earley & Ang, 2003; Pinkley & Northcraft, 1994). Consistent with this idea, Chinese Americans, who are familiar with both Chinese and American cultures, are likely to know that Americans have higher promotion pride than do Chinese. Therefore, when Chinese Americans try to persuade a Chinese or American to purchase an insurance policy, they use more promotion-focused arguments for an American target than for a Chinese target (Leung et al., 2003).

Third, accurate knowledge of another culture is linked to better intercultural interaction quality. For example, among Mainland Chinese university students in Hong Kong, some have more accurate knowledge of the values of their host culture (Hong Kong culture) than others. Those who have more accurate knowledge have more satisfactory interactions with the local students and the university staff than do those who have less accurate knowledge (Li & Hong, 2001).

In summary, as bicultural experiences accumulate, so does bicultural knowledge. Bicultural knowledge can foster culturally competent behaviors and creative endeavors. However, as noted, individuals who have acquired knowledge from a second culture may or may not identify with the second culture. If that is the case, how do biculturals negotiate cultural identity?

MANAGEMENT OF MULTICULTURAL IDENTITIES

Cultural identities may be uniquely represented within each multicultural individual (Roccas & Brewer, 2002). Based on how multiple cultures are structurally represented, there may be little competition for psychological resources among cultural identities. However, even though there may be little internal conflict *within* multicultural individuals, the differing demands and expectations placed on members of each cultural group—to be culturally authentic, to be loyal to the group, speak the language, and follow the norms, along with numerous others—necessitate management of situation-appropriate responses.

Successful management of multicultural identities thus involves resolution of conflicts arising from these manifold internal and external demands. Thus, management of multiple identities requires both overt and conscious flexibility (Birman, 1998; Phinney & Devich-Navarro, 1997), along with more subtle adaptability to the cultural requirements of the situation (e.g., changes in field dependence [Kitayama, Duffy, Kawamura, & Larsen, 2003]; self-esteem levels [Hetts, Sakuma, & Pelham, 1999]). Additionally, it entails increased proficiency in choosing among identity options to emphasize the desirable aspects of the self in context (Spratt, 1994; Waters, 1990). Although numerous means of managing multiple cultural identities are available to multiculturals, possible limitations exist as to the scope of management strategies employed. Depending on prescribed social policies within a society (e.g., Berry, 2001), attitudes toward multiculturalism held by the majority or dominant group (e.g., LaFromboise, Coleman, & Gerton, 1993; Montreuil & Bourhis, 2001), or available personal resources (e.g., Camilleri & Malewska-Peyre, 1997), individuals may negotiate their multiple identities through integration, alternation, or synergy strategies. Although engagement in multicultural identity negotiation may yield overt behaviors in tune with changing cultural environments, management processes may also generate internal ambivalence regarding identity loyalties and cultural affiliation.

Multicultural Identities and Their Development

Recent acculturation models (e.g., Lee, Sobal, & Frongillo, 2003; Ryder, Alden, & Paulhus,

2000; Tsai, Ying, & Lee, 2000) have emphasized the multidimensionality of cultural selves: As individuals acquire knowledge and practices of a new culture, knowledge and practices of heritage cultures are retained. Moreover, these cultural identities can coexist within any given individual without adverse psychological consequences.

Furthermore, individuals may strategically evoke cultural identities to enhance their consonance with changing environments. As Padilla and Perez (2003) point out, in adapting to a new cultural context, newcomers may engage different identity strategies depending on contextual factors such as the cultural and racial diversity of the place of settlement, the dominant group's assignment of value to the identities brought by newcomers from their prior experiences, or the extant relations among dominant and nondominant groups prior to their arrival. Importantly, these contextual factors contribute to newcomers' motivations to acculturate to the mainstream culture.

The foregoing analysis implies that multiculturals may *develop* and *adjust* their multicultural identities in response to changing circumstances to increase the alignment of the identities with individuals' prior experiences, and current goals and affordances. This developmental perspective to multicultural identities has two major advantages. First, many writers have focused on the hypothesized negative consequences of identity shifts. Terms such as "culture shock," "acculturative stress," and "identity confusion" are illustrative of the negative slant with which multicultural identity management has been addressed. From the developmental perspective, these seemingly negative experiences grow out of the awareness of cultural differences and the deliberate effort to retain or reformulate the current identity in light of new cultural experiences. These "negative experiences" surface only at certain transitional stages of multicultural identity development.

Second, a developmental perspective demands attention to identify and analyze the processes involved in the construction and management of multicultural identity. Recent studies have captured a few snapshots of these processes. Coming in contact with different cultural traditions increases self-awareness of one's own cultural embeddedness (Sussman, 2000; Zaharna, 1989). This heightened aware-

ness then allows one to make comparisons, to distance oneself, or to choose from among available cultural identity options (Camilleri & Malewska-Peyre, 1997; Verkuyten & de Wolf, 2002). With prolonged contact, individuals may develop adjustment repertoires that in turn lead to sustained identity shifts or the internalization of new cultural identities. Once multiple identities are internalized, proficient management of multiple identity demands requires that complex knowledge structures associated with each cultural identity—episodic memories and meaning systems composed of values, beliefs, behaviors, practices; significant others and acquaintances—be appropriately accessed in changing contexts, while new cultural knowledge is concurrently encoded into memory. Smooth management of such complex multicultural identity processes may be facilitated by increased sociopolitical support for multicultural societies (Berry, 2001) in which individuals would have ready access to many different ways of negotiating multicultural identities. As individuals gain greater access to multicultural-oriented life experiences, different identity-management strategies, which were initially intentionally and effortfully controlled, may be practiced at a relatively automatic or nonconscious level.

Strategies of Multicultural Identity Negotiation

Every multicultural identity may have a unique developmental history and a distinct developmental trajectory. Nonetheless, existing research and theory on multicultural identity negotiation may be organized into three broad categories of identity negotiation strategies: integration, alternation, and synergy. Preference for identity negotiation strategies may change over the life course, and any given individual may synchronously utilize all or a combination of these three distinct modes of identity negotiation.

In one class of identity negotiation models, *integration*, identities become blended and merged into one coherent identity (LaFromboise et al., 1993; Sprott, 1994). Integration models assume that elements from multiple cultures fuse into a unitary (multicultural) identity. As such, integration models view the development of multicultural identities as additive, in that new cultural identities are “added to” existing cultural identities. However, elements from one culture may be cued in differ-

ent circumstances, bringing to the fore, relative to other internalized cultures, aspects of the self associated with the cued culture. Integration models often describe multiculturals as having highly developed identities in each culture, which are utilized in culturally appropriate ways in different contexts (e.g., Oyserman, 1993; Oyserman, Sakamoto, & Lauffer, 1998; Suinn, Ahuna, & Khoo, 1992; Yamada & Singelis, 1999).

The second class of negotiation models, *alternation*, involves switching back and forth among cultural identities depending on the fit of the identity with the immediate context. Ross et al. (2002) showed that when responding in Cantonese or Mandarin, bilingual-bicultural Chinese Canadians shifted their self-descriptions toward a pattern typical of Chinese than when responding in English. Hong and her colleagues have also demonstrated that biculturals readily shift cultural interpretive frames based on available cultural cues (Hong et al., 1997, 2000, 2003; No & Hong, 2004a). Although cultural knowledge is indeed distinct from cultural identity, it would not be a stretch to assume that aspects of the self are also accessed and applied in response to cultural cues.

In the third class of negotiation strategies, *synergy*, entirely new identities are forged as a result of contact with different cultural models (Anthias, 2001). In contrast to integration or alternation, synergy posits that new identities emerge which cannot be reduced to the sum of their parts (e.g., Benet-Martinez, Leu, Lee, & Morris's [2002] notion of a “third culture”). As an example, in our new line of research on cultural hybridization (No, Wan, & Chiu, 2005), we posit that Korean American culture (or Chinese American culture, etc.) is not a direct summation of components from Korean culture (i.e., the culture of Korea) and American culture (i.e., the culture of the United States), but rather is a unique cultural configuration that results from a transformation of the components themselves when they interact with one another. As such, an individual who identifies as Korean American embodies an entirely new set of knowledge traditions, one that arises and unfolds in a specific historical context of ethnic Koreans residing in an American landscape. In the domain of language, synergy is best encapsulated in the process of creolization, in which a new grammar is constructed out of the continued interaction of groups speaking two or more distinct languages. In this respect,

Grosjean (1989) notes that it may be inaccurate to transport paradigms of neurolinguistic research developed from monolingual speakers to that of bilingual speakers. Bilinguals must instead be approached as a person with a “unique and specific linguistic configuration . . . and not the sum of two monolinguals” (p. 6). By acknowledging the unique and specific effects of bilingualism, linguistic research has been extended to examine phenomena such as code switching and language borrowing. Furthermore, Grosjean argues that the synergistic effects of bilingualism do not entail a loss of competency in the original languages—an idea that resonates with research on cultural hybridization (e.g., Korean Americans are to some extent culturally competent in Korean culture and in American culture).

Identity Ambivalence, Marginalization, and Alienation

In an early analysis of migration and identity, Park (1928) approached the internal conflict and ambivalence arising from identification with multiple cultural groups through the notion of “marginal man,” a person who feels simultaneous detachment and involvement with multiple cultural groups. Identification with multiple cultural groups engenders psychological conflict when values and practices of heritage and mainstream cultural groups are perceived to be too distant or in opposition (Benet-Martinez et al., 2002). Identity ambivalence may also result from the fluctuating responses of others to multiculturals, depending on the salient identity features of a context (Turner, Hogg, Oakes, Reicher, & Wetherell, 1987), such as when multiculturals are approached with intimacy and familiarity in one context and responded to with fear and distance by the same individuals in another context (Zaharna, 1989). Additionally, identity conflict may arise due to exclusion or rejection by desired cultural groups. Exclusion is then turned inward and attributed to lack of cultural knowledge or language fluency (Kanno, 2003; Pang, 2000).

Identity ambivalence, marginalization, and alienation may also result from intragroup conflicts among newly arrived and established cultural groups who settle within the same geographical area. Feeling excluded by the established group increases the likelihood that migrants develop ambivalent or marginal identities. Niemann, Romero, Arredono, and Ro-

driguez (1999) found that U.S. Mexicans perceived more rejection and discrimination from Chicanas/Chicanos (U.S.-born Mexican Americans) than from Anglo Americans. Japanese Peruvians and Japanese Brazilians who traveled to Japan as migrant workers during the late 1980s and throughout the 1990s were treated as Peruvians/Brazilians by the Japanese, but as Japanese in their respective countries of Peru and Brazil, although of mixed blood and being of second- or third-generation status (Tsuda, 2003; Takenaka, 1999).

Psychological Adjustment to Bicultural Experiences

Berry and his colleagues (Berry, Poortinga, Segall, & Dasen, 1992; Berry & Sam, 1997) have put forth an influential model of acculturative strategies. As individuals come in contact with multiple cultural groups, they may accommodate their identity to the mainstream culture (*assimilate*); simultaneously retain their heritage cultural identity, while developing the mainstream cultural identity (*integrate*); reject the mainstream cultural identity, opting instead for their heritage cultural identity (*separate*); or reject both mainstream and heritage cultural identifications (*marginalize*). Berry hypothesizes that integration is most conducive to psychological well-being, although the evidence for this hypothesis is inconclusive (Rogler, Cortes, & Malgady, 1991; Rudmin, 2003).

A key issue seems to be the generation cohort of the immigrants. For instance, Furnham and Li (1993) found that second-generation Chinese in Britain, who were more likely to report feeling that they were part of the host community, were significantly more likely than those who did not feel part of the host community to report greater psychological symptoms. Similarly, Robins and Regier (1991) found that the lifetime prevalence of mental illness of U.S.-born Mexican Americans was much higher than that of first-generation Mexican American immigrants. Organista, Organista, and Kurasaki (2002) thus suggested that the poorer mental health of native-born Mexican Americans, despite their greater assimilation into the U.S. culture than first-generation Mexican Americans, “has to do with their especially stressful experience in America as a devalued and discriminated ethnic minority group” (p. 154).

Aside from focusing on the acculturation strategy per se, some researchers have examined the cognitive factors that underlie vulnerability in adjusting to bicultural experience. For one, Benet-Martinez and Haritatos (2005) found that Asian Americans who view their Asian identity and American identity as conflicting showed greater depression and anxiety than do those who view their two identities as less conflicting. In other research, Hong and her associates (Chao, Chen, Roisman, & Hong, in press; No & Hong, 2004a, 2004b; cf. Hong, Roisman, & Chen, 2006) proposed that biculturals' beliefs about race—whether race is an essentialist entity (reflecting biological essence, unalterable, and indicative of abilities and traits) or a socially constructed, dynamic construct—predict the extent to which they can successfully achieve psychological adaptation to both cultures. The researchers argued that an essentialist race belief would give rise to perception of less permeability between racial group boundaries. Therefore, ethnic minorities holding an essentialist race theory would have a harder time integrating experiences with both their ethnic and host cultures. Consistent with this idea, Chao et al. (in press) found that the stronger the Chinese Americans participants endorse an essentialist race theory, the higher their skin conductance reactivity (sweating more compared to the rest period) when talking about their own bicultural experiences, suggesting that an essentialist race theory is associated with more effortful defense.

Summary

When multiculturalists negotiate cultural identity, they do not just retrieve their knowledge of the pertinent cultures. They turn cultural traditions into objects of reflection; they cognitively juxtapose these traditions and evaluate their significance with references to prior cultural experiences and current intercultural relations. Whereas the multicultural mind grows out of multicultural experiences, multicultural identity is both a product of deliberate reflectiveness and an ongoing personal project.

INTERACTION OF MULTICULTURAL KNOWLEDGE AND MULTICULTURAL IDENTITIES

Multicultural mind and multicultural identity are distinct constructs, but they do work to-

gether. This section explicates how cultural representations support a variety of cultural identification processes, including categorical perception, cultural identification, and affirmation of cultural identity. Next, we discuss how identification influences application of knowledge in specific multicultural contexts.

The Role of Cultural Representations in Cultural Identification

Cultural Prototypes and Categorical Perceptions

As noted, cultural identification involves defining the self with reference to one or more cultural traditions. Once cultural identification occurs, a person's perceptual focus shifts from the idiosyncratic characteristics of the self to the prototypical features of the culture (cf. Hogg, 2001, 2003). Prototypical features of a culture consist of symbolic elements (e.g., beliefs, values) and behaviors that epitomize the culture and maximally distinguish it from other cultures. In short, they are normatively agreed upon ideological and behavioral characteristics that define the culture. When identification with a culture is strong, or when cultural identity is made salient, perceptions of the social world are filtered through the lens of culture; thoughts and behaviors are not seen as signatures of individual personality, but are interpreted in terms of their consonance with cultural prototypes.

Thus, the varying degrees to which people's thoughts and behaviors adhere to cultural prototypes provide a gradient for differentiating and evaluating people (e.g., Haslam, Oakes, McGarty, Turner, & Onorato, 1995). Individuals who exhibit culture-prototypical thoughts and behaviors are perceived by other members of the culture to be good representatives of the culture, and are evaluated favorably. Conversely, those who exhibit culture-atypical thoughts and behaviors are often marginalized and evaluated negatively (Marques & Paez, 1994; Marques, Abrams, Paez, & Martinez-Taboada, 1998).

Cultural prototypes become a major criterion for interpersonal perception when cultural identification is strong, or when cultural identity is made salient. For example, in an organizational role-play experiment (McAuliffe et al., 2003), an employee showing collectivist behavior is perceived more positively than an employee showing individualist behaviors, when

the organization has a collectivist organization culture. This effect is particularly pronounced among those who strongly identify with the organization.

C. Wan, Chiu, Tam, et al. (2007) have proposed an intersubjective consensus approach to identifying culture-prototypical values. This approach involves assessment of the general consensus among people in the culture on the distributions of different values in the culture. Through their experiences in a culture, people learn about and even participate in the construction of the common beliefs and values that are important to the culture. Such collective representations do not necessarily correspond to most cultural members' private personal values (cf. Miller & Prentice, 1994). Yet when people in the same culture agree that certain values are widely shared in the culture, these values are likely to be culture-prototypical values. C. Wan and Chiu (2003) applied the intersubjective consensus approach to identify culture-prototypical values in an American undergraduate student culture and replicated the findings from the McAuliffe et al. (2003) study. Specifically, when their university student identity is made salient, student participants perceive a target student who endorses culture-prototypical values (values generally believed to be widely distributed in the student culture) to be friendlier, kinder, and more sincere than a target student who is not known to have these values (C. Wan & Chiu, 2003).

Cultural Prototypes and Cultural Identification

People may perceive others based on whether they display culture-prototypical values. They may also construct their own cultural identity based on how much they personally endorse culture-prototypical values: Individuals who endorse these values tend to identify with the culture, and those who do not have relatively weak cultural identification. Consistent with this idea, C. Wan, Chiu, Tam, et al. (2007, Study 1) found that university undergraduate students' identification with the undergraduate student culture is positively related to endorsement of culture-prototypical values identified through the intersubjective consensus approach. Analogous findings have been obtained in identification with other culturally constructed categories (e.g., gender [C. Wan &

Chiu, 2005]; political identification [C. Wan, Chiu, & Tam, 2005]).

Prototypical representations are also involved in identification with more than one culture. Consider the following two hypothetical cultures. Some values are prototypical features in Cultures A and B, but some are prototypical features only in Culture A, and others are prototypical features only in Culture B. Bicultural individuals know what values fall into each category. In addition, their relative strength of identification with the two cultures may be reflected in their relative endorsement of the different categories of values. Using the intersubjective consensus approach, researchers have been able to identify values that are prototypical features in Culture A but not in Culture B, and vice versa. In addition, it has also been shown that biculturals who identify strongly with Culture A (rather than with Culture B) tend to endorse values that are prototypical features of Culture A (C. Wan, Chiu, Peng, et al., in press).

Affirmation of Cultural Identity

When people identify with a culture, that culture heavily impacts their behaviors. Thus, people who identify strongly (vs. weakly) with a culture are more likely to follow cultural norms (Jetten et al., 2002, Study 1). For example, North Americans who strongly identify with North American culture are more individualist than are the weak identifiers. Similarly, Indonesians who strongly identify with Indonesian culture are more collectivist than individuals who weakly identify with the culture. Furthermore, when identification with a cultural group is strong, norms (shared attitudes) have greater impact on behavioral intentions than do personal attitudes, and the reverse is true when cultural identification is weak (Terry & Hogg, 1996; Terry, Hogg, & White, 1999).

When their cultural identity is threatened, people may attempt to affirm their cultural identity, often by asserting their adherence to cultural tradition. For example, research has examined how people respond to cultural identity threat. In this situation, high identifiers rate themselves as more collectivist when the cultural norm is collectivist than when it is individualist. Additionally, their behavioral intentions are more consistent with collectivist norms than are those of low identifiers (Jetten et al., 2002, Study 3).

Aside from identity threat, mortality salience may also increase the need to affirm one's cultural identity. Research has shown that when the terror of death is made salient, people manage their existential terror by asserting their membership in a valued cultural group, thereby endorsing the prototypical cultural values (Halloran & Kashima, 2004; Kashima, Halloran, Yuki, & Kashima, 2004; see review by Greenberg, Solomon, and Pyszczynski, 1997).

In summary, cultural prototypes as special kinds of cultural representations play an important part in a broad range of cultural identification processes, including categorical perceptions, cultural identification, and cultural identity affirmation.

Management of Multicultural Identities and Application of Multicultural Knowledge

The interaction between multicultural knowledge and multicultural identities has been most extensively studied in culture priming experiments. As mentioned, in culture priming, specific features of a social context activate certain piece of cultural knowledge, which is then applied in the specific situation. The presence of a cultural priming effect depends on the presence of knowledge about the culture being primed. Furthermore, how a piece of cultural knowledge is related to people's specific responses to cultural cues depends on their identity management concerns in that situation (Chiu & Chen, 2004). Specifically, multicultural individuals, in any given context, may show an assimilation or a contrast response to the cued culture. When knowledge of both cued cultures is available, contextual cues can push biculturals' responses in the direction of the cued culture, producing an assimilation effect (Hong et al., 2000; Wong & Hong, 2005). However, when cultural identity is made salient, or when one's cultural identity is under threat, the motivation to affirm one's cultural identity may drive a contrast effect. Under this circumstance, contextual cues may push biculturals' responses away from the cued culture. For example, presenting highly Welsh-identified Welsh speakers with speech samples of British Standard English may lead these speakers to exaggerate their Welsh accent when their minority status is also made salient in the situation (Bourhis & Giles, 1977).

The likelihood of displaying an assimilation or contrast effect is also related to how

biculturals cognitively represent the pertinent cultures. Biculturals may perceive their two cultural identities as compatible and integrated, or as conflicting and separate (Benet-Martinez et al., 2002). Chinese American biculturals who perceive their Chinese and American identities as compatible tend to show an assimilation effect, whereas those who perceive their Chinese and American identities as conflicting tend to show a contrast effect. Apparently, when two cultural identities are perceived to be compatible, cultural cues do not evoke strong reactance, and biculturals display responses consistent with the activated cultural frames. However, when biculturals feel that they are torn between two conflicting cultures, cultural cues may elicit psychological reactance and produce a contrast effect.

According to Benet-Martinez et al. (2002) the perceived compatibility between two cultures is an important determining factor in whether biculturals integrate the two cultural identities into one, combined, emerging identity. Consistent with this proposal, research has suggested that the bigger the perceived distance between two cultures, the more difficult it is for cultural travelers to acculturate into the second culture (e.g., Dunbar, 1994; C. Ward & Searle, 1991).

Another factor that predicts the tendency to display assimilation or contrast effects is the extent to which biculturals believe that "race" is an essentialist entity, which we already discussed briefly (No & Hong, 2004a, 2004b). When Korean Americans hold an essentialist belief about race, they tend to view the boundary between their own ethnocultural group and the mainstream group as impermeable. The mainstream American icons remind them of their minority status (i.e., "I am a Korean") and the Korean cultural values associated with their minority identity (No & Hong, 2004b). Therefore, instead of displaying an American response pattern, they show a response pattern that is consistent with the highly accessible Korean identity. For example, North Americans are more likely to show egocentric projection of emotion (e.g., "Others must feel sad too when I am sad") than are East Asians, who in turn are more likely than North Americans to show relational projection of emotion (e.g., "Others must feel sympathetic when I am sad"; Cohen & Gunz, 2002). Korean Americans who believe in an essentialist race theory show an increased tendency to make relational projec-

tion subsequent to being primed with American cultural icons, an indication of contrast effect (No & Hong, 2004a).

To summarize, when identity issues are not involved, culture priming produces an assimilation effect. However, when identity issues are brought into the scene, more complicated response patterns emerge, suggesting that culture primes do not just call out the corresponding cultural knowledge. Instead, they increase awareness of the intercultural relations in the society, activate perceptions of the identity compatibility and malleability, and evoke feelings and values attached to one's cultural identities. All these effects take place within an intercultural context, embedded within a broader network of power relations in the society.

GLOBALIZATION AND THE REMAKE OF THE CULTURAL LANDSCAPE

Thus far, our discussion has focused on the basic principles of multicultural psychology, which explain the molecular processes in multicultural psychology. However, a complete analysis of multicultural psychology demands attention to a critical analysis of the embeddedness of individual psychology in a rich historical and political multicultural context. Cultural psychology has barely set foot on this intellectual territory. Yet this may be the territory where theories of multicultural psychology will meet new challenges.

With the rapid growth of global linkages and consciousness, social life is increasingly organized on a global scale. Human beings have entered the era of globalization. Both the referential and connotative meanings of *globalization* may vary, depending on the context in which the term is used. However, most writers agree that globalization involves "the compression of the world and the intensification of consciousness of the world as a whole" (Robertson, 1992, p. 8).

As globalization proceeds, more previously isolated economies are integrated into the world economy via international trade and investment. Some countries, such as China, have benefited enormously through this process of integration and have enjoyed rapid growth in gross domestic product (GDP). However, there is also ample evidence that the gap between the richest and poorest countries, and that between

the richest and poorest groups of individuals in many nations (including the most industrialized states; e.g., the United States and Western European countries) have increased (Alderson & Nielsen, 2002). For instance, within an industrialized country, the problem of income inequality has been aggravated by direct investment outflow, import of cheaper consumer goods and, to a lesser extent, inflow of international labor through migration (Alderson & Nielsen, 2002). These developments make it necessary to conceptualize negotiation of cultural identities within the confines of power relations in both local and global contexts.

At the same time, the rapid speed of air transportation, and the instantaneous electronic transfer of information and capital, have led to what Anthony Giddens (1985) refers to as time-space distanciation, or the experiential compression of time and space. A postmodern, global culture is often characterized as one "of virtuality in the global flows which transcend time and space" (Castells, 1998, p. 350). Increasingly, the forces that have grounded different knowledge traditions to a confined space have disintegrated.

As the pace of globalization accelerates, so does population movement across national borders. At the beginning of this chapter, we presented some statistics on migration. Migration influences the ethnic composition of both the sending and receiving countries. Many migrants are *temporary* international workers (e.g., Filipino domestic helpers in Hong Kong, seasonal farm laborers) who move from one country to another and back again. Business travel and tourism are two other major components of population movements. For example, Canada has a population of about 31 million people but has close to 50 million entries by nonresident travelers annually. Similarly, the United States receives approximately 97 million international travelers annually by air alone (Richmond, 2002).

The demographic changes accompanying globalization have important implications for the coordination of knowledge and negotiation of identities in cosmopolitan cities. To begin, globalization requires integration of local economies into the global market, which is grounded in the capitalist logic. The capitalist logic is grounded in "instrumental rationality," a kind of rationality defined in terms of efficiency and feasibility of achieving goals via calculative strategization of the means (Weber,

1904/1958). Instrumental rationality flourished in Europe during the Enlightenment period, when a coalescence of individualist ideas became popular. These ideas include religious individualism (the emphasis on the individual's personal relationship with God, and the belief that salvation is contingent on personal faith and needs no intermediaries), economic individualism (the belief that rewards depend on individual performance), political individualism (the belief that political systems are set up to satisfy individual needs, and that individual rights are protected by law), methodological individualism (the belief that all social phenomena should be understood as resulting from the psychological processes of individuals), and psychological individualism (the belief in the value of the individual, self-actualization, individual uniqueness, and individual identity; Ho & Chiu, 1994; Lukes, 1973). This collection of ideas constitutes the major contents of the mainstream knowledge tradition in most industrialized countries, consisting of the United States and most Western European countries. The question is: Will globalization ultimately lead to homogenization of cultures via *global hegemony*?

Globalization and Homogenization of Cultures

At first glance, the global hegemony project is destined to succeed. The Western economic powers, representatives of the global market force, may have a dominating influence over other, non-Western (local) nations not only in the economic sphere but also in the direction of cultural restructuring. Globalization has been labeled as new, modern, scientific and results-oriented. The global culture embraces consumerism, individualism, competition, and efficiency. These cultural ideals could be falsely established as universal, overriding local traditions. The hegemonic influence seldom takes the form of enforced domination. Instead, it often assumes the form of voluntary submission to the reference culture (van Strien, 1997). In addition, the capitalist logic in the global market demands strict adherence to the same collection of efficient economic and social practices that turn out controllable, predictable results. Furthermore, an expanding consumerist culture, with its attendant global marketing strategies, tends to exploit similar, basic material desires and create similar lifestyles (Parameswaran, 2002).

There is some evidence that globalization may lead to the demise of local cultures. First, a defining feature of globalization is the continuing transformation of the society via science and technology (Fischer, 1999). Penetration of science and technology education, which supports and is in turn supported by instrumental rationality, is a hallmark of globalization in a country. In a comparative study of 20 nations that differ widely in the extent of globalization (e.g., from Sweden to Romania, Brazil, Mexico, and Thailand), Tzeng and Henderson (1999) reported that the best country-level predictor of the level of globalization is the country's level of involvement in science education. Countries with more mature global economies have greater educational expenditures per capita, a higher percentage of the adult population with college-level education, a greater number of university professors per capita, a greater number of foreign students in national universities, and a greater number of students attending institutions of higher learning abroad. In addition, people in countries with more mature global economies have stronger identification with the value of scientific education.

There is some tentative evidence that exposure to the global culture, directly via exposure to global industries such as tourism, or indirectly through participation in a science and technology educational institution, may lead to the demise of indigenous knowledge traditions. In one study, participants from Kenya and the United States responded to the TST, which requires the participant to generate 20 self-descriptive statements. Among pastoral nomads in Kenya, only 18% of their spontaneous self-descriptions referenced personal attributes. The remaining 82% of their self-descriptions referenced memberships in social categories. By comparison, the percentage of self-descriptions that referenced personal attributes was 42% for hotel workers and university staff in Kenya, 83% for university students in Kenya, and 87% for American undergraduates (Ma & Schoeneman, 1997). There is also evidence that, compared to Japanese students who have never been abroad, students who have visited a Western country report higher self-esteem (Heine, Lehman, Markus, & Kitayama, 1999).

However, findings from the kind of comparative studies described in the previous paragraph are difficult to interpret because of self-selection bias. For example, in the study con-

ducted in Kenya, it is possible that college students, as well as workers in hotels and universities, belonged to a self-selected sample with a strong preference for the global knowledge tradition or a cosmopolitan (vs. tribal) identity. Thus, their American-like responses to the TST could be expressions of their identity choice rather than indentations caused by globalization's inevitable erosive effects.

Globalization and Cultural Diversity

Some writers contend that globalization will not result in homogenization of culture. Lal (2000) offers a distinction between material and cosmological beliefs in a culture. "Material" beliefs pertain to ways of making a living or beliefs about the material world, particularly the economy. By contrast, "cosmological" beliefs are related to the definition of humankind's place in the world. More specifically, cosmological beliefs define the purpose and meaning of life, and an individual's relationship to others. Whereas the material beliefs in the global culture increase in popularity as a country is integrated into the global market, cosmological beliefs in local knowledge traditions are relatively resistant to the influence of globalization.

There is some evidence for this hypothesis. Based on data from the three waves of the World Values Surveys, which include 65 societies, Inglehart and Baker (2000) found that economic development is associated with increased endorsement of values that emphasize secularism, rationality, and self-expression. However, the broad knowledge tradition of a society (e.g., Protestantism, Confucianism) leaves an imprint on work-related values (e.g., importance of good pay, job security, work pressure, trade union, working with pleasant people) that endures despite the erosive effects of globalization.

Fu and Chiu (2003) also found that among Hong Kong undergraduates, with globalization, Western values compatible with instrumental rationality (e.g., creativity) have high cognitive accessibility. By comparison, Western moral values rooted in political individualism (e.g., liberty and human rights) are less accessible. In the moral domain, Confucian values of interpersonal mutuality continue to enjoy high cognitive accessibility. In short, instead of homogenizing culture, globalization may lead to *pluralization* of cultures via the meeting of global and local cultures in one locality.

The presence of plural cultures may result in internal *differentiation*, with one segment of the population favoring the traditional culture and others favoring the emerging new cultural modes and lifestyles. For example, globalization has brought about contested views about females in India. On the one hand, in Hindu patriarchal beliefs, the female gender is essential and primordial (Mahalingam, 2003). In one study, American and Indian participants were asked to imagine that a man's brain was transplanted to a woman's head, and vice versa. Most American participants believed that a brain transplant would change the gender behaviors of both a man and a woman. By contrast, most Indian participants, particularly Brahmin males, believed that a brain transplant would change the gender behaviors of men only, and that women are biologically predisposed to behave in a feminine manner; they would exhibit feminine qualities that even the most radical medical intervention could not have altered (Mahalingam & Rodriguez, 2003).

On the other hand, globalization has brought new educational and employment opportunities to women in India, reducing their reliance on husbands and fathers. In addition, as documented in an in-depth ethnographic study in West Bengal, India (Ganguly-Scrase, 2003), in promoting a consumerist ideology, the mass media have created a new consumerist subject—a glamorous "liberated" woman that epitomizes independent mobility through shopping. In Bengal, whereas older women favor the traditional Indian view of womanhood, many younger women use images of the new consumerist subject to construct new models of womanhood that stand in opposition to the traditional patriarchal gender norms and challenge the gender ideologies in Bengali culture.

Globalization has been characterized as a process that generates contradictory spaces (Sassen, 1998), because the spread of the global culture may provoke resistance and reactions from local cultures. The *contestation* of global and local cultures could range from out-and-out rebellions against globalization (e.g., the antiglobalization demonstration that took place in Seattle during the World Trade Organization Conference in 1999) to engagement in practices that embody oppositional local cultural meanings. For example, Thompson and Arsel (2004) studied local coffee shops in Chicago as the embodiment of such oppositional

cultural meanings in stark contrast to global cultural meanings that Starbucks represents. Some of these local coffee shops are decorated with countercultural symbols and bohemian atmospherics, whereas others exhibit a more polished, bourgeois ambiance. Some regular patrons of these coffee shops denounce Starbucks for crowding out all the local coffee shops, and view local coffee shops as exuding an alternative, antiestablishment aura, and as outposts for like-minded activists to challenge prevailing corporate power structures.

Contestation of global and local cultures may also result in adaptation of norms or practices to local traditions, a process often referred to as *glocalization*. In the marketplace, the globalized capital seeks complete domination (Parameswaran, 2002). The shopping mall is an outpost of the globalized economy. Because a high percentage of malls are planned and built by no more than 10 transnational architectural firms, malls throughout the world share common features of aesthetics, architecture, and design. For this reason, the shopping mall is also an architectural symbol of globalization. However, as Salcedo (2003) noted, even in the shopping mall, which has been assumed to be an archetypical globalized space, aspects of the local culture are co-opted into the world of consumption. For example, in the Philippines' Megamall, there is a church constructed for Catholic masses. In Saudi Arabia, there is a mall where foreign women perform the sales work and men are prohibited to enter.

In summary, although there have been some concerns that globalization might undermine cultural diversity through the processes of pluralization, contestation, and glocalization, there are also reasons to believe that globalization will foster cultural diversity.

The Political Context of Identity Negotiation

Identity negotiation is a historically constituted process. Processes such as colonization, globalization, and racial tensions are integral parts of the context of identity negotiation. Take colonization as an example: By the time of World War I, the European powers ruled over 85% of the rest of the globe. The world map has changed drastically since then, as the world order is reconstituted in response to the aftermath of the world wars, the civil and ethnic wars following them, and the collapse of the Communist Bloc. Many former colonies have

established national independence. However, the impact of colonization on cultural identity negotiation can still be felt in some neo-Colonial regions.

For example, Réunion, an island in the Indian Ocean, was uninhabited when the Portuguese discovered it in 1513. From the 17th to the 19th centuries, French immigration supplemented by Africans, Chinese, Malays, and Malabar Indians gave the island its ethnic mix. The plantation workers, many of whom were slaves, spoke different languages and were obliged to communicate through Creole, a linguistic intermediary easily understood by all. Gradually, Creole cemented relations between different ethnic components in the slave society; the Creole identity became a common identity built around the Creole language and bound together heterogeneous cultures. Today, "creolization" is used in cultural discourse to refer to the process whereby a human group attempts "to create a new local culture from the whole range of cultural resources available to the different components that together constitute a creolized society" (Medea, 2002, p. 127).

In 1946, Réunion entered the neo-Colonial era when the island became a French département. Since then, the French government has implemented a series of assimilation policies emphasizing French culture and denying the worth of the Réunionese people's language, values, and culture. The cultural assimilation process was accompanied by the imposition of a globalized economy, dominated by the service sector, with its consequent focus on consumption, international finance, banks, and multinational corporations. These changes have rejuvenated the identity negotiation process on the island. For example, cultural movements to assert a distinctive Creole identity emerged (Medea, 2002), bringing around a continuous contestation of the global French culture and the local Creole culture.

In a multicultural environment, cultural clashes may lead to adoption of separatist strategies in identity management, whereas countries in the wake of severe racial antagonism may seek to replace exclusionist identities with an inclusive one. South Africa's social history provides a good illustration of both processes. After the South African government publicly admitted the failure of apartheid policies in 1989, an immediate issue was how to find a cultural identity that would promise

unity and reconciliation after decades of racial tension and cultural clashes. Against this historical backdrop, South Africans rediscovered the biblical symbol of the rainbow to represent peaceful harmonization of different racial and cultural traditions. In 1994, Archbishop Desmond Tutu proclaimed proudly in a televised Thanksgiving service: "We are the rainbow people of God. We are free—all of us, black and white together!"

The rainbow people identity is both an inclusive identity and a political symbol, consciously crafted to achieve a political purpose. It is an identity defined by a peaceful union of diverse cultural and racial traditions. Survey research in South Africa revealed initial strong support for the rainbow people identity. In 1994, 65% of South Africans favored the rainbow people identity, but the percentage of supporters dropped to 48% in 1999. In 1996, 17% of South Africans considered the rainbow people identity a source of national pride, but the percentage dropped to 11% in 1999 (Dickow & Moller, 2002). The waning appeal of the rainbow people identity casts doubt on the efficacy of using an inclusive identity to manage diverse cultural groups in a multicultural nation.

Compared to the ethnic relations in South Africa, ethnic relations in the United States, albeit more subtle, are by no means less influential in shaping the course of multicultural identities negotiation. On the one hand, the widely held ideology of American culture being a "melting pot" has exerted pressure on ethnic minorities to assimilate into the American mainstream culture (see Hirschman, 1983). On the other hand, research has shown that ethnic/minority Americans are less likely than white Americans to be seen as full-fledged members of the society. For example, Devos and Banaji (2005) found that the category "American" is associated with being white for most white respondents. Similarly, Cheryan and Monin (2005) found that white American perceivers consider Asian American faces less American than white American faces. More important, the Asian Americans, made aware of this perception, may react to it by asserting their American identity. For instance, in one experiment (Cheryan & Monin, 2005, Study 5), a white experimenter subtly denied Asian American participants' American identity by telling them at the beginning of the experiment, "Actually, you have to be an American to be in this study." This manipulation led Asian Amer-

ican participants to exhibit behaviors that affirmed their American identity.

Many minority group members in the United States are sensitive to both the differentness and the disadvantageousness of their ethnic cultural tradition. Here is how a Vietnamese American informant in an ethnographic study expressed her frustration: "I have been here 18 years and if somebody had been to Viet Nam and spoke the language would think they knew that country well . . . [but] Americans still think of me as a foreigner" (Sparrow, 2000, p. 188). With the awareness of their differentness and disadvantageousness, some minority group members have sought to fit into the mainstream culture by developing a secondary cultural identity, as revealed in the report of another informant in the same ethnographic study: "As a result of all these differences and having been forced to adapt to this new culture, I have developed another cultural identity which is capable of surviving in this new environment. . . . This identity functions like a second personality that appears when it is necessary to adopt a culturally appropriate behavior in the new culture" (p. 192). The same themes of ethnocultural discrimination, the desire to preserve the heritage cultural tradition, consciousness of the benefits of biculturalism, and motivation for bicultural identity development also emerged in an ethnographic study of a Chinese community in Chicago (Lu, 2001).

For Japanese in Brazil, the turns of events in the global context changed their social status in Brazil and the way they managed their multicultural identities (Tsuda, 2001). Japanese migration to Brazil began at the beginning of the 20th century, when the Brazilian government decided that Japanese workers were technologically minded enough to work in Brazil's expanding coffee plantations. Encounters with the ethnically and culturally different Brazilians heightened the salience of the imported workers' Japanese identity.

The rise of Japan as a global imperial power in the 1930s fueled an anti-Japanese movement in Brazil. The tide of anti-Japanese sentiment rose as Japan entered World War II. In response to their negative minority status, some Japanese in Brazil began to adopt the majority cultural patterns in exchange for better acceptance into majority society. As a result, a synthetic bicultural identity known as Japanese Brazilian emerged and gained popularity among the Brazilian-born Japanese.

After World War II, Japan rapidly rose to the top of the global order to become the second largest economy in the world, thereby reversing the hierarchical relationship between Brazil and Japan on the global scale. As Japan rose in global prominence and prestige, Japanese Brazilians started to embrace their Japanese cultural heritage and distance themselves from the undesirable, underdeveloped aspects of Brazil's culture. The result has been a reaffirmation of their Japanese identity after decades of assimilative attempts to become more Brazilian.

Ironically, when the Brazilian economy crumbled in the 1980s, some Japanese Brazilians, attracted by the abundance of job opportunities, migrated to Japan, only to discover that they would be treated as "foreigners" in their "homeland." They were seen to have been "Brazilianized," and were socially and culturally marginalized. By immigrating to Japan, these Japanese Brazilians had subjected themselves to a new set of power relations and were obliged to participate in a new round of cultural identity negotiation (Tsuda, 2001).

In short, the cases described here illustrate the historical constitution of cultural identity. Each country or group has its unique social and political history, and has therefore followed a distinctive course of cultural identity development. The goal of the review in this section is not to delineate the universal principles that govern negotiation of cultural identities. On the contrary, our goal is to highlight the complexity of such negotiation processes, and how such processes may change course in response to the changing power relations in the society. Nonetheless, the examples reviewed here illustrate the multiplicity of cultural traditions represented in the mind of individuals in a globalized world, and the sociopolitical dimensions that underlie negotiations of multicultural identities. These are the two recurrent themes that have emerged from the rapidly expanding empirical literature we reviewed in previous sections.

CONCLUDING REMARKS

Hong et al. (2000) have proposed a dynamic constructivist approach to studying the influences of multiple cultures on individuals. At the heart of this approach is the idea that all individuals are capable of representing multiple

cultures in their minds and switching between representations of cultures. As such, culture should not be seen as a static, monolithic entity. Instead, it should be understood as a collection of variably shared knowledge representations that people use to navigate the social world. Accordingly, culture should not be treated as synonymous with a demarcated population defined with respect to certain demographic, geographic, national, or ethnic characteristics. We acknowledge that meanings are unevenly distributed in different cultural groups, and that such uneven distribution of meanings may give rise to stable, meaningful, between-group differences (see review by Lehman, Chiu, & Schaller, 2004). However, the presence of such differences does not justify a reified and essentialist view of culture.

The dynamic constructivist approach conceptualizes the multicultural mind and multicultural identity as distinct but interrelated theoretical constructs. Acquisition of knowledge from a new culture does not always produce identification of that culture. Accordingly, although the global culture is spreading rapidly around the world, homogenization of cultures is not an inevitable outcome of globalization. Indeed, multiculturalism and globalization are likely to coexist.

The increased frequency and intensity of intercultural contacts will inevitably change the agenda of cultural-psychological research. On the one hand, knowledge of multiple cultures can be a valuable resource; individuals with a multicultural mind are equipped with several sets of interpretive tools to grasp experiences. We have reviewed how exposure to other cultures is linked to increased creativity and competence in intercultural interactions.

On the other hand, experiences with multiple cultures can also raise identity concerns, particularly in situations where individuals need to pledge their allegiance to one or the other cultures. The identity negotiation processes often take place amid the power relations in the society. There is a pressing need for cultural psychologists to address these processes as they redefine the intercultural and intergroup landscape in the coming decades.

NOTE

1. We endorse the view that culture consists of a network of loosely organized knowledge that is produced,

distributed, and reproduced among a collection of interconnected individuals (Chiu & Chen, 2004; Shore, 1996; Sperber, 1996). According to Barth (2002), knowledge constitutes “all the ways of understanding that we use to make up our experienced, grasped reality” (p. 2), and includes all learned routines of thinking, feeling, and interacting with people.

CHAPTER 14

Cultural Psychology of Workways

JEFFREY SANCHEZ-BURKS
FIONA LEE

The domain of work constitutes a major portion of our lives. A study conducted by the Economic Policy Institute found that the average worker in the United States spends 1,900 hours a year, roughly a third of one's total waking hours, at work. Furthermore, the number of hours individuals spend at work has steadily increased in the United States (e.g., a typical person works 20 days more a year than 25 years ago; Linstedt, 2002; Wessel, 2003). This trend of increasing hours at work is also documented in the European Union, despite social and political efforts to resist such trends (Frost, 2005). These figures do not take into account working hours outside the office; with the proliferation of telecommunication technologies, it is not uncommon for people to handle work-related e-mails, paperwork, and phone calls at home, during their commute, or while on vacation (Barker, 1998). Given work's dominant claim on people's daily lives, understanding the cultural psychology of *workways* is critical to understanding the cultural psychology of social life. Workways describe a culture's signature pattern of workplace beliefs, mental models, and practices that embody a society's ideas about what is true, good, and efficient within the domain of work.

How much cultural variability is there in workways? Some have suggested that trends in business globalization may have reduced cross-cultural differences in workways; as a result of efforts by multinational corporations to standardize structures and tasks, as well as the large percentage of managers getting their training from U.S. business schools, or programs modeled after U.S. business schools (Hébert, 2005), cultural variance in workways in contemporary organizations is minimized and subsumed by the larger "business" culture. According to this view, the world of work increasingly serves as a "culture free or culture neutral zone" (Birnbaum-More & Wong, 1995).

However, these claims about the cultural universality of workways are not supported by recent empirical evidence showing that cultural differences are amplified rather than diminished in work contexts (e.g., Sanchez-Burks, 2002). As we describe later in this chapter, several studies have shown that East-West differences in relational attunement—sensitivity to social, emotional, and relational cues—are more prominent in work than in nonwork settings (Sanchez-Burks et al., 2003). Far from being culture neutral, work-

ways remain deeply colored by the palette of historical, ideological, and sociocultural influences that operate in the larger societal context, and may well be a domain that amplifies these dynamics.

Research showing that cultural divides widen within the workplace can be problematic from a practical standpoint. Intercultural contact is often necessary at work, where fluent communication and coordination must occur in the face of deep-seated cultural differences. Within major U.S. cities, for instance, about one-fourth of the population was born in a foreign country (e.g., 36%, Los Angeles; 25%, Boston; 21%, Chicago, and about 11% of the U.S. population, or 26 million individuals; U.S. Bureau of the Census, 2000), such that most individuals have little choice but to interact with colleagues, suppliers, and customers of different cultural and ethnic backgrounds. Increases in cross-cultural contact at work also stem from the recent increase of multinational corporations; many large corporate mergers have united companies from different cultures (e.g., Daimler–Chrysler, Ericsson–GTE, Hitachi–GE), creating an environment where people from different cultures have to cooperate, communicate, and coordinate closely and effectively.

Indeed, there is general recognition by business researchers and practitioners that cultural differences in workways can create problems in job performance, that cultural differences are not well understood, and that they are difficult to manage. For example, the business press is rife with stories of successful managers assigned to an international post and failing spectacularly to replicate their success at home. Approximately 15–50% of managers assigned to work with colleagues abroad curtail their assignments because of an inability to manage cultural differences in interpersonal behaviors, such as receiving and giving feedback, communicating criticisms and differences in opinion, and expressing emotions at work (Bird, Heinbuch, Dunbar, & McNulty, 1993; Copeland & Griggs, 1985; Deshpande & Viswesvaran, 1992; Eschbach, Parker, & Stoeberl, 2001; Tung, 1987). These failures of intercultural work directly affect businesses' bottom lines, with each failure costing an estimated \$50,000 to \$350,000 (Copeland & Griggs, 1985). From an applied perspective, there is tremendous interest in understanding how cross-cultural differences and dynamics

affect interpersonal processes in the workplace, as well as specific interventions organizations can enact to diminish problems and misunderstandings that arise from such differences.

In this chapter, we lay an initial groundwork for a cultural psychology of workways. In doing so, we draw from a variety of research in social, organizational, and cultural psychology—for example, studies examining workplace relational styles, dynamics of intercultural contact, managerial and organizational perceptions, and social networks—to discuss how these dynamics reflect on cultural theory and research. Attention is given to how work affects cross-cultural dynamics, as well as how cross-cultural dynamics affect work. To the extent that both culture and work are important sources of context for individuals, this chapter also has broader implications for understanding the relationship between the individual and the context.

The reviews included in this chapter are not exhaustive but are intended to highlight emerging characteristics of the cultural psychology of workways. These characteristics include (1) greater attention to historical, ideological, and sociocultural influences that create, maintain, and transform approaches to work; (2) a focus on the specific cognitive and behavioral mechanisms that produce cultural variation at work; and (3) increased emphasis on research that produces rich accounts of culture-specific workways. We begin by tracing historical accounts of culture and work.

LOOKING BACK: HISTORICAL PERSPECTIVE ON CULTURE AND WORK

The domain of culture and work is not a new to scholarly inquiry. The earliest written accounts of cultural variation, dating around the 6th century B.C., describe the unique social patterns of merchants as they traded along the shores of the Black Sea, and how the diversity of cultural practices affected this work (Ascherson, 1996; Herodotus, 2003). Similarly, the emergence of unique workways was one of the defining features of early America (Crèvecoeur, 1782/1981; de Tocqueville, 1840/1990). Historically, accounts of culture and work have been characterized by two constant and defining themes that remain central to the cultural psychology of workways: attempts to understand how cultural beliefs shape the con-

text of work, and how the context of work influences cultural beliefs (Fiske, Kitayama, Markus, & Nisbett, 1998).

Debates over Influence of Structure versus Beliefs

Work played a dominant role in the 19th-century debates about the influence of “macro” social–organizational structures on beliefs (Marx, 1873/1992) versus the influence of “micro” beliefs on social–organizational structures (Weber, 1904/1930). For Karl Marx, the structural conditions of the workplace produced particular psychological states (e.g., alienation) that form the basis of sociocultural worldviews and workways. Although Max Weber did not directly disagree with this perspective, he argued that prevailing cultural ideologies played a key role in creating culturally unique workways. For example, he argued that the early (17th and 18th centuries) Calvinists believed that work was part of a religious calling and was valuable in its own right, that idle talk and sociability was distracting to one’s work duties, and that individuals ought to maintain an unsentimental impersonality at work (Bendix, 1977; Fischer, 1989; Landes, 2000). In cultures influenced by this theology, such as the United States, these beliefs about work were secularized and incorporated in the contemporary culture, so that attitudes such as valuing work in and of itself, relying on the self, and limiting personal indulgences are not merely representative of Calvinist Protestants but largely descriptive of Americans as a whole (Furnham, 1990; Lenski, 1961).

Causal evidence of this mutual constitution of context and mind was convincingly provided through a series of influential studies carried out a century later by sociologists Kohn and Schooler (1983). Supporting the influence of social structure on psychology (e.g., Marx, 1873/1992; Whyte, 1956), their studies showed that features of one’s occupational context (e.g., the relative complexity of one’s job and the degree of self-direction in organizing tasks) have a direct influence on people’s beliefs and behaviors that extends beyond the closing workday’s whistle. Moreover, they provided evidence of a reverse causal path whereby individual-level cognitions and personality characteristics shape the conditions of work (particularly over extended periods of time), suggesting that psychology also influences social structures (e.g., Bellah, Madsen, Sullivan,

Swidler, & Tipton, 1996; McClelland, 1961; Weber, 1904/1930).

Sociocultural History in Cultural Theory

Early studies on culture and work typically focused on a society’s social history, describing how historical practices and ideologies sowed the seeds for contemporary cultural patterns. Similar to the notion of path-dependence used by economists (e.g., Arthur, 1994), the origins of contemporary cultural workways were traced to prior social-historical events or conditions rather than to factors in the immediate, current environment (for reviews see Arthur, 1994). This, of course, was central to Weber’s (1904/1930) thesis on the Protestant work ethic (PWE); as mentioned earlier, Weber traced beliefs in the United States about the value of work, limits to self-indulgences, and self-reliance to the ideologies of the founding Calvinist communities in 17th-century New England. Other studies showed how sociocultural practices perpetuated these culturally unique belief systems through the generations. For example, Winterbottom (1953) compared the child-rearing practices of Protestant and Catholic mothers in the United States and found that Protestant mothers spent more time communicating PWE values and motivations (cf. McClelland, 1961), and introduced them at earlier ages in their child’s development.

As a matter of historical coincidence, a different movement around the same period introduced a similar notion of hard work as moral imperative in Japan. Robert Bellah (1957) argued that early religious beliefs during the Tokugawa period (1600–1868) in Japan left a lasting imprint on contemporary Japanese workways. Particularly, Bellah showed that early doctrines of Buddhism, Confucianism, and Shintoism encouraged ways of thinking that underlie Japan’s contemporary economic and industrial development. For instance, early cultural emphasis on the family fostered the emergence of many small, family-owned enterprises. Similar to development of the PWE in the United States, secular and religious beliefs mutually influenced each other. On the one hand, religious values that placed political and family leaders in the realm of the “divine” encouraged compliance to government policies and interventions directed to spur industrialization. On the other hand, hard work and self-

sacrifice were viewed as ways to achieve religious enlightenment. As Bellah (1985) argued, the central value system that developed in the Tokugawa period remains influential in contemporary secular Japanese culture, perhaps in a more intense form.

The lasting effects of social history on culturally unique workways extend beyond moral imperatives toward hard work and self-sacrifice. For example, Schooler (1976) found that cultural variations in self-direction and authority orientation in the workplace could be predicted by when a cultural group's ancestral country abolished serfdom and hence changed the "macro" work context (e.g., England in 1603, German states in 1815, Poland in 1861). This trend was observed after controlling for social class, occupation, and religion. In other words, contemporary cultural differences in workways reflected sociocultural conditions generations ago. These studies demonstrate the importance of investigating the influence of a group's prior social-historical conditions on the development and availability of specific psychological beliefs and attitudes.

The Study That Spawning a Movement: Hofstede at IBM

The spark that ignited a widespread interest in culture and work was a multinational survey study of IBM employees (Hofstede, 1980). By focusing on self-reported preferences for work-related characteristics, Hofstede sidestepped complex issues regarding the role of social-historical conditions, ideology, or the mutual influence of context and mind in constituting cultural workways. Hofstede proposed that national cultures vary along four dimensions: (1) *power distance*, or an individual's preference for equality–inequality between individuals in a group; (2) *uncertainty avoidance*, or an individual's preference for structure; (3) *masculinity/femininity*, or an individual's prevalence for assertiveness, performance, success, and competition (masculinity) versus quality of life, warm personal relations, service, care for the weak, and solidarity (femininity); and (4) *individualism versus collectivism*, or an individual's preference for acting as an individual or acting in a group.

Of course, these dimensions did not originate with the publication of Hofstede's *culture's consequences*; themes about individual versus community or equality versus inequality

were discussed much earlier by many social scientists (e.g., Durkheim, 1933; Mead, 1967; Parsons, Bales, & Shils, 1953; Reisman, 1961; Whyte, 1956; Tönnies, 1887/2002; Kluckhohn & Strodtbeck, 1961). Hofstede's study, however, launched a widespread research interest in cross-cultural industrial–organizational psychology (for excellent reviews, see Hui & Luk, 1997; Earley & Gibson, 1998). Furthermore, despite the study's exclusive focus on work settings, Hofstede's dimensions of culture became a dominant framework for understanding cross-cultural differences across virtually all settings, work and nonwork alike.

(Back) Toward a Cultural Psychology of Workways

Despite decades of research focusing on cultural variation along broad value dimensions such as individualism–collectivism or power distance, there is a paucity of valid, reliable evidence that these dimensions can explain (i.e., mediate or moderate) distinct psychological or behavioral outcomes (Briley & Wyer, 2001; Earley & Mosakowski, 2002; Heine, Lehman, Peng, & Greenholtz, 2002; Takano & Osaka, 1999; but see Earley, 1989, for an exception). More recently, cultural scholars have focused on the specific cognitive structures and processes that guide behavior (Morris & Young, 2002), and linking these cognitions to social-historical and contextual features unique to a cultural group (Sanchez-Burks, 2002). This strategy of combining methodological advances in social-cognitive psychology with the rich social-historical approach of earlier cultural psychology has developed more precise, richer models of cultural workways. Specifically, this involves taking into account the role of context, as well as specific mental schemas, and mapping out the conditions under which one expects both cultural differences and similarities. We review examples of this work in subsequent sections of this chapter.

WORKPLACE RELATIONAL STYLES

Culturally Specific Workplace Relational Styles

Although the majority of cross-cultural psychology emphasizes cultural comparisons, examining how two or more cultures differ along any number of variables, one prevailing stream of research in cross-cultural psychology of

work has examined culturally indigenous or culturally unique workplace relational styles. “Workplace relational styles” refer to people’s beliefs about the function of relationships in the workplace, as well as relational behaviors at work (e.g., communicating with others, attending to another person’s needs). This more anthropological approach of examining, in depth, unique patterns of interpersonal relating within a single culture has identified a number of culturally specific workplace relational styles that reflect deep-seated ideologies about the nature of social–emotional ties within and across work domains (e.g., Ayman & Chemers, 1983; Diaz-Guerrero, 1967; Earley, 1997; Markus & Kitayama, 1991; Triandis, Marin, Liansky, & Betancourt, 1984).

Chaebol

Organizational research within South Korea suggests that work relations are modeled after the tradition of *chaebol*, or “company familism” (Kim, 1988). Here, work relationships are not unlike family relationships. Managers or work supervisors play a paternal role in relation to their subordinates (Hui & Luk, 1997). In this way, work organizations are typically a network of tight-knit, highly personal relationships. Variations of *chaebol* can be found in other Asian cultures, such as Japan and India (Hui, Eastman, & Yee, 1995; Kanungo, 1990; Kool & Saksena, 1988; Sinha, 1980). Managers in these cultures take care to learn about the personal lives of their subordinates; attend the “personal” events of employees, such as a relative’s funeral; and actively intervene on behalf of their employees in personal affairs, such as marital problems or family finances (Triandis, Dunnette, & Hough, 1994). Similarly, an employee’s sense of obligation to his or her boss extends beyond the boundaries of the office or workday. Subordinates are expected to assist their bosses at work, but the boss should expect the subordinate similarly to provide assistance outside of work, and for non-work-related tasks such as household chores or assisting in family events (Hampden-Turner & Trompenaars, 1993).

Guanxi

In Chinese organizations, business relations are characterized by a distinct emphasis on building dense networks of personal relationships.

Entrepreneurs conduct their business by developing *you-yi*, or deep friendships based on mutual obligation in which business people make connections in their social networks available to one another (Solomon, 1999; Wall, 1990). This Chinese system of dense networks, or *guanxi*, differs from networking in Western businesses because of its transitive nature (Cai, 2001; Farh, Tsui, Xin, & Cheng, 1998; Li, Tsui, & Weldon, 2000). Whereas a French businessperson interested in connecting with a target person in a fellow French colleague’s network might typically ask the colleague to facilitate such a connection, a Chinese operating under the principle of *guanxi* would assume that he or she has direct access to any person in the colleague’s network. Thus, more than using common network ties as a way to create familiarity and a base for generating goodwill, *guanxi* describes the transitive nature of obligations in Chinese business practices.

Guanxi also influences preferences for business partners. For example, rather than making business decisions based on “objective” measures, such as price, product quality, or technical skills, it would not be uncommon for a Chinese businessperson to do business with another person more because he or she comes from the same village or has a mutual acquaintance. These social “contracts” are seen as reassurances that a business partner will indeed be reliable and trustworthy (Sanchez-Burks, 2005). For many Asians, establishing *guanxi* is an essential condition to an effective working relationship (Hampden-Turner & Trompenaars, 1993).

Simpatía

Like most other relationships, work relations in Latin cultures are guided by the relational script of *simpatía* (Diaz-Guerrero, 1967; Triandis et al., 1984). Similar to many East Asian cultures, *simpatía* emphasizes social harmony, such that respecting and understanding others’ feelings is valued above all, and conflict is minimized (Markus & Lin, 1999). Unlike many East Asian cultures, *simpatía* also emphasizes the expressive displays of personal charm, graciousness, and hospitality—even to those outside one’s personal networks (Diaz-Guerrero, 1967; Lindsley & Braithwaite, 1996; Sanchez-Burks, Nisbett, & Ybarra, 2000). *Simpatía* is a valued characteristic in many Latin cultures, even within the workplace. For

example, within Italy, it has been found to be a necessary (though not sufficient) prerequisite to leadership (Dechert, 1961).

Protestant Relational Ideology

Although the culture-specific relational styles reviewed thus far—*chaebol*, *guanxi*, and *simpatía*—all suggest a heightened emphasis on relationships at the workplace, research on American workways shows a different pattern. Specifically, American workways are guided by *Protestant relational ideology* (PRI), an ideology that combines Lutheran teachings about the importance of work with Calvinist imperatives for restricting relational, social-emotional concerns while working (Sanchez-Burks, 2002). As put in practice by the early Calvinists, these restrictions were relaxed outside of work such that paying attention to others' social-emotional cues was considered entirely appropriate at play and leisure (Daniels, 1995; Fischer, 1989). Thus, PRI is characterized by a divide in relational attunement, or attention to affective issues and relational concerns, between work and nonwork contexts (Bendix, 1977; Lenski, 1961). Specifically, relational attunement among Americans is reduced in work settings compared to social, nonwork settings (Sanchez-Burks, 2005).

The social-historical origins of PRI were demonstrated in an experiment comparing levels of relational attunement in work versus nonwork settings between two American samples with highly similar demographic profiles (socioeconomic background, educational background, religiosity) but differed in whether their religious upbringing was connected to PRI (Protestant) or not (non-Protestant) (Sanchez-Burks, 2002, Study 1). Participants were primed for either a work context or a nonwork context, then performed an "emotional Stroop test" in which they heard positively or negatively valenced words read in an affect-appropriate tone (e.g., a sad voice for funeral) or an affect-inappropriate tone (e.g., a sad voice for wedding). Participants had to identify the semantic valence (good-bad) of each word and ignore the emotional tone of the spoken word. When primed for the nonwork context, emotional tone of voice equally confused both Protestant and non-Protestant groups (i.e., when the tone was affect-inappropriate, participants took longer to identify the semantic valence of the word). How-

ever, when primed for the work context, emotional tone of voice had significantly less effect for the Protestants compared to the non-Protestant participants; the Protestant participants were better at blocking out emotional content, but only in the work context. It appears that Protestant and non-Protestant Americans had different workplace relational styles: Whereas the non-Protestants attended to emotional content in both work and nonwork contexts, Protestants limited their processing of emotional cues in the work context only.

This pattern was replicated in a study that examined levels of nonconscious behavioral mirroring, a behavior that reflects attention to another person in the relationship (Sanchez-Burks, 2002, Study 2). Participants with a Calvinist religious upbringing did not engage in nonconscious mirroring of another person when primed with a work context. However, non-Calvinist participants in work and nonwork contexts, as well as Calvinist participants in nonwork contexts, all showed higher levels of mirroring. Again, being at work or in a work relationship appears to reduce relational attunement and sensitivity for Americans raised in a Calvinist tradition. Though secular American culture in general is strongly affected by Calvinistic teachings (Bendix, 1977; Daniels, 1995; Fischer, 1989; Lenski, 1961), these studies show that the influence of PRI on workways seems particularly pronounced for those raised in this religious tradition.

Culturally Indigenous Workplace Relational Styles: A Summary

Taken together, research on workplace relational styles shows tremendous diversity in the mental models people use to navigate and manage relationships in the workplace. Some workplace relational styles, such as *chaebol*, *guanxi*, or *simpatía*, rely on a heightened sensitivity to interpersonal relationships in the workplace. In cultures where these workplace relational styles are dominant, being at work often may require attention on two foci—the task at hand (e.g., the budgetary implications of a proposal being presented by a coworker) and the relational dimension of the social interaction (e.g., coworkers' nonverbal gestures that unfold while they describe the proposal). Of course, this heightened relational attunement serves only as a basic building block upon which such

diverse forms of workways as *chaebol* or *simpatía* are possible.

In contrast to these work patterns based on heightened relational attunement, American workways appear as an exception, characterized in part by a relational style in which affective and relational concerns are less carefully monitored and are given diminished importance. As we describe in the next section, this pattern of behavior is specific to work. Outside work, Americans are just as attentive to social-emotional cues as East Asians. This moderating role of context highlights both cultural differences and cultural similarities in workways.

It is important to note that workplace relational patterns are reflected in variables across multiple levels of analysis, from cognitions to behaviors to social network structures. For example, *chaebol* describes family-like relationships in the workplace, *guanxi* is about the use of informal relationships at work, *simpatía* emphasizes display of and attention to subtle relational and social-emotional cues at work, and PRI is about the separation of work and nonwork relationships. In the next section, we turn to research describing workplace communication and feedback, dynamics that further reflect cultural workways in general, and cultural variation in workplace relational attunement in particular.

Relational Attunement and Indirectness in Workplace Communication

“Relational attunement,” or attention to affective issues and relational concerns, is often examined in the context of communication. Specifically, people’s awareness and comprehension of subtle or indirect cues in interpersonal communication are often used as an indicator of relational attunement (Earley, 1997; Holtgraves & Yang, 1992; Ting-Toomey, 1988). Grice (1968) differentiated between “sentence meaning,” which refers to the literal or semantic meaning of an utterance, and “speaker meaning,” which refers to what the speaker intends to accomplish with the remark. Relational attunement can be seen as sensitivity to discrepancies between sentence and speaker meaning.

From the speaker’s point of view, relational attunement can be defined as the speaker’s intention to do more than merely transmit the literal or sentence meaning of the words exchanged (Grice, 1968). Indeed, speakers can

use a wide variety of subtle communication cues to transmit indirect meaning (Brown & Levinson, 1987; Goffman, 1959). For example, one can convey criticism of a colleague’s work by avoiding eye contact (nonverbal), offering faint praise (verbal indirect meaning), or using a critical tone of voice (verbal emotion; Ambady, Koo, Lee, & Rosenthal, 1996; Lee, 1993; Goffman, 1967). Similarly, relational attunement can be used by speakers with more malevolent or devious intentions, for example, in the form of subtle sarcasms that protect one from accountability for negative remarks (DePaulo & Kashy, 1998).

From the listener’s point of view, relational attunement can be understood as the listener’s awareness of and attention to subtle communication cues to infer speaker meaning. Imagine a man talking to a colleague about his new supervisor. He mentions that she seems nice and fair. His colleague laughs, shrugs his shoulders, and says, “Well, yes, I suppose she *is* nice and fair. Best of luck to you.” If the listener is relationally attuned, he or she will be able to “read between the lines” and likely conclude from the colleague’s verbal tone and gestures that the new supervisor is probably a very difficult boss. In contrast, if the listener is not relationally attuned, he is less likely to use and attend to subtle communication cues, more likely to expect themselves and others to communicate more directly or “say it as it is,” and only attend to the explicit meaning of what is said (Holtgraves, 1997). Using this example, the listener is likely to infer from the colleague’s statement that the new supervisor is indeed a nice and fair person.

Avoiding misunderstanding therefore requires that communicators have similar levels of relational attunement. For example, if the colleague is using indirect cues and nonverbal gestures to convey his message that the new supervisor is a difficult boss, but the listener assumes that the comments can be interpreted literally, misunderstandings can occur (Brown & Levinson, 1987; Earley, 1997; Lee, 1993; Prentice & Miller, 1999). We next describe cultural research on relational attunement, focusing on studies of indirect communication and nonverbal communication at work.

Indirectness

One common assumption is that East Asians are more indirect in their communication than

Westerners. Because East Asians are presumably more attentive to maintaining face for others, they are more likely to “couch” the meanings of their words with subtle verbal and nonverbal cues, and to pay attention to these cues in interpreting others’ speech (Earley, 1997; Lee, 1993, 1999; Ting-Toomey, 1988). However, recent studies on indirectness suggest this may not always be the case. Sanchez-Burks et al. (2003) used self-report and implicit measures of indirectness to compare managers in the United States, China, Korea, and Singapore. The self-report measure was a modified version of Holtgrave’s (1997) indirectness questionnaire, in which respondents indicated their use of indirect cues in communication within work and outside of work. The behavioral measure of indirectness asked respondents to interpret the meaning of a message communicated between either two friends or two coworkers; here, indirectness refers to going beyond sentence meaning to infer speaker meaning.

The study found the expected cultural difference in indirectness in work settings; Chinese and Koreans managers were more indirect (both as speakers and as listeners) than their American counterparts at work. For example, when asked to interpret the performance feedback, “There is room for improvement but overall this is good,” East Asian managers were more likely to infer that this message was feedback given for relatively poor performance, whereas American managers did not go beyond the explicit meaning of the message and inferred that this message conveyed a relatively positive assessment. However, no reliable cultural differences in indirectness were found outside work settings. For example, when asked to interpret the same message framed as a discussion between two friends about a personality test, American managers were just as indirect as East Asian managers (see Figure 14.1).

According to the dynamic constructivist perspective of culture (Hong, Morris, Chiu, & Benet-Martinez, 2000), cultural interpretive frames or schemas guide behaviors only when they come to the foreground (i.e., become available, salient, and applicable) in the individual’s mind. In this sense, cultural differences are dynamic and context-dependent. Consistent with this perspective, cultural differences in indirectness vary depending on the contextual cues that make different relational styles

FIGURE 14.1. Indirectness as a function of context and participant’s culture. Adapted from Sanchez-Burks et al. (2003). Copyright 2003 by the American Psychological Association. Adapted by permission.

more or less accessible. Within the context of work, American managers activate a particular relational schema that diverges from that of their East Asian counterparts. However, outside the context of work, American and East Asian managers adopt similar relational schemas in their use of indirectness.

Nonlinguistic Cues

We found similar moderating effects of context in research on nonverbal communication at work. Ambady et al. (1996) compared how Korean and American managers use nonlinguistic cues in their workplace communications. American and Korean managers were videotaped communicating good news (getting an unexpected bonus) or bad news (losing an expected bonus) to either a boss, a peer, or a subordinate. Content-filtered versions of these videos were rated by Korean or American coders for use of nonlinguistic cues.

The results showed that, compared to Americans, Korean managers were more sensitive to the hierarchical nature of the relationship and modified their use of nonlinguistic cues as a function of this relationship. For example, Korean managers were rated as using more nonlinguistic cues when the listener was higher in status; they were more likely to exhibit nonlinguistic cues that communicated other-enhancement, affiliation, and self-deference when communicating to a boss than to a peer

or a subordinate. In contrast, American managers did not vary their use of nonlinguistic cues to bosses, peers, or subordinates. However, American managers were influenced by the content of the message, using more nonlinguistic cues when communicating bad news than good news. Korean managers, on the other hand, did not vary their use of nonlinguistic cues based on the content of the message. Overall, the results demonstrated that Korean managers showed higher levels of relational attunement than American managers in hierarchical situations, whereas the reverse was true when the content of the message was particularly negative.

Although this study only examined within-culture communication (the raters of nonlinguistic cues were from the same culture as the managers who produced the cues), the observed cultural difference can be a source of misunderstanding and misinterpretation in the workplace. For example, when Korean speakers use a lot of nonlinguistic cues to signal the higher status of the listener, American listeners might mistakenly interpret these cues to mean the content of the message is extremely negative. Or when American speakers use a lot of nonlinguistic cues to signal extreme criticism, the Korean listener might mistakenly interpret these cues to reflect merely the listener's relative status, rather than as a signal for the severity of the situation.

Relational Attunement at Work: A Summary

Relational attunement is of critical concern in the multicultural workplace. As mentioned, when speakers and listeners have different norms of relational attunement, misunderstandings and misinterpretations of information can easily occur. The research evidence we have reviewed shows that cultural influences in relational attunement are complex; specifically, culture interacts with context in different ways to influence relational attunement. Cultural differences in relational attunement can be more apparent in some situations than in others (e.g., in work vs. nonwork contexts, or when transmitting good vs. bad news), or more apparent in some relationships than in others (e.g., in hierarchical relationships).

This raises several implications. First, though cultural *differences* have been the focus of much cultural theory and research, these studies also highlight cultural *similarities*, de-

scribing contexts and situations in which people from different cultures do not behave differently from one another. These complex interaction effects between culture and context are all too often overlooked in efforts to array cultures along broad value dimensions. Second, the nature of these cultural patterns and interactions appears better explained by specific psychological mechanisms—deep-seated beliefs and cognitive processes—that are not always accessible to participants. This idea that internal cognitive or affective systems are differentially brought to the fore as situational cues change is similar to other conceptions of how personality differences are moderated by context (Mischel & Shoda, 1995). Third, this work has particular relevance for practice. To the extent that work often requires effective communication between people of different cultural backgrounds, it is critical to understand the conditions in which discrepancies in relational attunement are especially large. This concern with managing and minimizing problems in intercultural interpersonal contact is particularly salient when considering issues of diversity, to which we turn our attention next.

MANAGING DEMOGRAPHIC AND CULTURAL DIVERSITY

Diversity is a large topic of research in the organizational and management literature (for a review, see Williams & O'Reilly, 1998). Diversity, as it has been studied, relates to issues around the management of demographic differences—to what happens when people of different gender, nationality, age, functional expertise, education, tenure, religion, and ethnicity relate to one another in the context of work. Although psychologists have long tackled this problem by focusing on issues such as prejudice, stereotyping, and discrimination, organizational researchers also are interested in the question of whether demographic diversity leads to better outcomes (Chatman, Polzer, Barsade, & Neale, 1998).

There are many reasons why a demographically diverse workforce might enhance work-related effectiveness and productivity. Given the increasingly diverse marketplace—both globally and locally—firms must be able to sell to different types of customers and work with different types of vendors to remain competitive in the long run. Firms that have a diverse

workforce are presumably better able to take advantage of the opportunities of the global marketplace and thrive (Williams & O'Reilly, 1998). A related argument suggests that work units—firms or teams—that bring together different opinions, perspectives, backgrounds, and expertise are more likely to generate creative and innovative ideas, which are critical for long-term survival and success of the firm (e.g., Jehn, Northcraft, & Neale, 1999; Lau & Murnighan, 1998).

However, the evidence that demographic diversity leads to more effective work performance has been, at best, mixed. Though demographic diversity can enhance task effectiveness in complex environments—as diversity brings about more approaches, perspectives, and opinions—it also increases emotional conflict within the work unit (Brief, 2000). Indeed, extensive research on intergroup dynamics suggests that mere contact between groups often gives rise to adverse dynamics such as implicit and explicit ethnocentrism, outgroup stereotyping, and intergroup hostility (R. Brown, 1986). The increase in interpersonal and social conflict that results from demographic diversity tends to undermine task effectiveness (Jehn, 1995), and this does not abate until the minority group reaches a critical mass (e.g., in traditionally male professions when women represent close to 50% of the work unit; Allmendinger & Hackman, 1995). Although the potential promise of demographic diversity has not been borne out by research, several streams of research on cultural workways suggest a new approach to defining and theorizing about diversity.

Demographic and Work Styles Diversity

The research literature on diversity most commonly focuses on the demographic features of individuals (e.g., ethnicity, nationality, age, gender) as the source of interpersonal difference and, therefore, conflict. An implicit assumption in this literature is that people's category membership is the primary form of diversity at the workplace. This focus, unfortunately, overlooks another potentially more important form of difference, namely, cultural variations in the mental models and relational styles people bring to the workplace. Organizational researchers have focused on differences in observable demographic characteristics, with little attention to the substantive differ-

ences that lie underneath them, whereas cultural psychologists have generated rich theory and empirical data on cultural variations that could make a difference in the workplace.

Work Team and Coworker Preferences

Recent research on work team preferences has taken initial steps to bridge these streams of work. Social and organizational psychologists have argued that ingroup biases stemming from a social categorization process create a preference, when given the choice, to work with others who have similar category membership (e.g., functional background, age group, nationality, gender, ethnicity; Pelled, 1996; Chatman et al., 1998; Williams & O'Reilly, 1998). For example, provided the opportunity to choose between an Anglo or a Latino workgroup, an Anglo worker is more likely to choose the Anglo workgroup.

However, surface-level demographic characteristics are confounded with culturally specific relational schemas; for example, people's cognitions and behaviors about appropriate relational behaviors at work tend to reflect their cultural or ethnic group memberships. In a study that disentangled these relative influence, Sanchez-Burks et al. (2000) asked participants to choose between two groups—an ethnic ingroup that exhibited a work style of an ethnic outgroup, and an ethnic outgroup that exhibited a work style of an ethnic ingroup. The results showed that 85% of participants showed a preference for the ethnic outgroup. In other words, similarity in working style was far more important than similarity in ethnicity *per se* in choosing teams and coworkers.

This finding suggests that preference for one's own ethnicity actually might reflect a preference for a certain culturally bound work style. It may be difficult to assess in actual work settings, however, whether a discriminatory action against an outgroup member reflects an ethnic bias or a working style bias. Nonetheless, to the extent people automatically infer a particular working style (or any other characteristic) simply based on another person's ethnicity, the consequences of both types of prejudice are similarly insidious.

The idea that working style, rather than ethnicity, is a more powerful shaper of people's decisions about what team to join or with whom to work can offer a different approach to reducing prejudice and discrimination. Focusing

too narrowly on demographic characteristics as the source of minority disadvantage runs the risk of missing the underlying mechanism of the prejudicial behavior (i.e., working style incongruence). If given substantive information about other people's work styles, observers may be less likely to rely on demographic categories such as ethnicity as a heuristic to infer work styles, and thus less likely to rely on these demographic categories to guide their preferences and choices of teams and colleagues (e.g., Sanchez-Burks et al., 2000).

Implications for Mentor–Protégé Relationships

In addition to work team and coworker preference, diversity also has implications for mentor–protégé relationships. According to research on leader–member exchange theory (Graen, Novak, & Sommerkamp, 1982; Paglis & Green, 2002; Sherony & Green, 2002), superiors rather quickly identify subordinates with whom they will form informal mentoring relationships. Demographic biases have been shown to have an important role in these decisions, often to the detriment of minority demographic groups (e.g., Pelled & Xin, 1997). In the United States, for example, male managers tend to form mentoring relationships with male rather than female protégés, or white managers tend to form mentoring relationships with white rather than nonwhite protégés (Thomas, 1993). Given that mentoring relationships are considered an essential resource for climbing the corporate ladder, many scholars and practitioners have suggested that women and ethnic minorities are inherently at a disadvantage because of this type of prejudice and discrimination in the corporate world.

However, supervisors' early preferences for subordinates actually might reflect preferences for work style similarity rather than demographic similarity. Lacking other information about these relatively new employees who are potential protégés, it is not unreasonable for supervisors to infer working styles based on demographic characteristics such as ethnicity—particularly given the substantive overlap between working styles and membership in different cultural demographic groups. However, as actual working styles of protégés' become developed and apparent over time, mentors might seek out mentoring relationships with people who share their own working styles regardless of demographic congruence. Similar to

work group or coworker preferences, it might be the case that given substantive information about working styles, mentors will pick protégés not primarily based on demographic congruence, but rather on congruence in working styles. Nonetheless, the implication of this shift in preference from ethnicity to relational work style does not necessarily alleviate problems of intergroup bias. To the extent that relational styles of the dominant group remains favored over those more common among underrepresented cultural groups, this cultural-psychological perspective on workways suggests the possibility of an overlooked, nuanced form of institutional discrimination.

Extreme Diversity and Hybrid Cultures

Further evidence that diversity can be conceptualized as managing differences in work styles (rather than demographic group membership) comes from an innovative study by Earley and Mosakowski (2000). In a series of experiments with four-person managerial teams that worked within a large multinational firm headquartered in Bangkok, they varied the level of cultural diversity represented in the teams. The results replicated an expected effect in which split teams (two members from one country, and two members from another country) experienced more negative dynamics and performed worse compared to homogeneous teams (all members sharing a common nationality). But they also formed teams that had "extreme" levels of diversity—in which each member came from a different country—such that no two members held a common cultural background. These teams with extreme levels of diversity performed better than split teams and did just as well as the homogeneous teams. As Earley and Mosakowski observed, in the absence of any common cultural work styles or schemas, these highly diverse teams created a hybrid culture in which team-specific norms, rules, and expectations emerged. In short, extreme levels of demographic differences allowed these teams, over time, to develop a new and shared work style, and this similarity of work style was a positive predictor of performance.

Interethnic Interviews

The consequences and implications of diversity are perhaps most controversial when one considers minorities' access to jobs and career mo-

bility. Overt and aversive racism continue to be a factor in hiring and promotion decisions within organizations today (Brief, 2000; Murrell, Dietz-Uhler, Dovidio, & Drout, 1994). An interviewer's ethnic biases can create a disadvantage for minority job candidates, even if these biases are not conscious or intentionally applied (Dovidio & Gaertner, 2000). A classic experiment on interethnic interviews conducted by Word, Zanna, and Cooper (1974) showed that nonconscious ethnic biases can be manifested in multiple ways; for example, white interviewers asked fewer questions, remained more physically distant, and made less eye contact during interviews with black candidates compared to white candidates. These differences create a self-fulfilling prophecy whereby the interviewer's ethnic biases negatively and nonconsciously affect the performance of the candidate.

However, perceived incompatibilities in the working styles of two cultural groups also can create disadvantages for minority targets or job candidates, creating conditions for what might be referred to as a *cultural incongruence prophecy* (Sanchez-Burks, 2005), which suggests that a target's behavior can be influenced by differences between the evaluator's and the target's culturally related cognitions. Evidence for this idea comes from a study examining nonconscious behavioral mirroring in the context of an interethnic job interview (Sanchez-Burks, Blount, & Bartel, 2007). Prior research shows that people have a nonconscious tendency to mirror others' behavior in social interactions, and that people have more positive subjective experiences of rapport as a result of mirroring exhibited by interaction partners (Chartrand & Bargh, 1999; Cheng & Chartrand, 2003; LaFrance, 1979). Both mirroring and its effect on perceived rapport are moderated by attentiveness to relational cues (van Baaren, Maddux, Chartrand, de Bouter, & Van Knippenberg, 2003).

Given that cultural groups differ in relational attunement (Sanchez-Burks, 2002), there should be cultural differences in the display and sensitivity to the effects of mirroring. Empirical evidence indeed shows that mirroring is more common within more relationally attuned, interdependent cultures compared to more independent cultures (van Baaren et al., 2003; van Baaren, Horgan, Chartrand, & Dijkmans, 2004), and these differences in the enactment of mirroring become pronounced

within work settings (Sanchez-Burks, 2002). More recently, Sanchez-Burks, Blount, and Bartel (2007) reasoned that Latinos' greater attentiveness to relational cues should increase their susceptibility to the negative effects of not receiving mirroring in a social interaction, whereas Anglo Americans' inattentiveness to relational cues at work would reduce their vulnerability to the negative experience of not receiving behavioral mirroring. They examined the implications of these differences in a field experiment in which Anglo American and Latino midlevel employees of a U.S. Fortune 500 company participated in a mock interview in a headquarters' office suite. Participants were randomly assigned to an Anglo American interviewer who mirrored, or did not mirror, the gestures, mannerisms, and postures of the applicants (while maintaining similar levels of propinquity and positivity, such as amount of smiling, across both conditions). The interviews were videotaped, and later an independent panel of professional recruiters and interview coaches, blind to the experimental conditions, evaluated participants' performances using these videos. The results showed that, overall, the absence of interviewer mirroring negatively affected all participants. More important, the performance of Latinos was more affected by mimicry than that of Anglo Americans; compared to those in the mirroring condition, Latino interviewees in the non-mirroring condition performed more poorly, and reported higher levels of anxiety and lower levels of self-esteem.

Although the mirroring of the interviewer in this study was experimentally manipulated, prior research showed that Anglo Americans are generally less likely to mirror or exhibit behavioral mirroring overall (van Baaren et al., 2003), and particularly in work settings (Sanchez-Burks, 2002). To the extent that most interviewers in corporate America tend to be Anglo Americans, this creates a naturally occurring environment in which Latinos would underperform in interview situations. These results suggest that differences in behavioral mirroring in the workplace, even in the absence of any overt or implicit racism against ethnic/minority groups, can result in outcomes that disadvantage the minority group. Adding to earlier themes of how a cultural perspective provides unique insights into intergroup biases, this research reveals how the workways of a dominant group operate as an institutionalized

form of discrimination, such that it does not require malevolent individual biases to create an inhospitable environment for minorities. In this way, even subtle differences in cultural workways can provide difficult challenges for facilitating diversity in organizations.

Managing Diversity: A Summary

In this section, we argue that marrying cultural psychology with diversity research is a fruitful endeavor. Although diversity has been typically examined in organizational research as differences in observable or surface characteristics (e.g., gender, race, or age), differences in less observable characteristics such as belief systems, preferences, work styles, and mental models also can be important factors that undermine intercultural contact. From a practical standpoint, interventions to increase diversity in the workplace can benefit from an increased focus on helping individuals to develop shared workways and workplace relational schemas across racial and ethnic lines.

As mentioned, the preference for and perpetuation of a dominant, culturally unique workway can be just as insidious as the preference for a dominant ethnic group. Organizational structures and practices, such as selection and attrition (Schneider, 1987), can reproduce and sustain a singular work style, mental model, or cultural ideology that undermines diversity in workways. For example, in a study of corporate recruiters of U.S.-based Fortune 500 firms, Heaphy, Sanchez-Burks, and Ashford (2007) found that job candidates who built rapport with an interviewer by blurring the work and nonwork divide (e.g., by mentioning a girlfriend or commenting on family pictures of the interviewer) were less likely to be granted a second interview. In other words, job candidates who do not conform to the uniquely American workway of restricting personal issues at work are less likely to be recruited. These institutional practices that reinforce homogeneity in workways do little to help business organizations reap the advantages of an ethnically diverse workforce. Of greater concern, given that workways are often culture-bound, organizations that pursue homogeneity of workways are also likely to bring about homogeneity of cultures and ethnicities. Indeed, organizations may justify or couch racially discriminatory hiring practices behind the more “politically correct” motivation of

preserving a singular workplace relational style.

On a more optimistic note, organizational change can play a role in facilitating larger cultural change. For example, in the dot-com boom of the 1990s, there are many examples of companies bucking normative traditions by embracing nonwork activities in the workplace—employees playing ping-pong during breaks at work, or going on whitewater rafting trips as a company. Or, as mentioned, as the marketplace becomes more global and companies become more multinational, it is increasingly a fact of life that employees have to adapt to and work with people with dramatically different workways. Echoing the ideas of Marx (1873/1992), individuals exposed to these different institutional environments are likely to develop different ways of working (e.g., different norms of blending work and nonwork activities) and may in turn be catalysts for bringing about larger changes in cultural ideology.

ORGANIZATIONAL AND MANAGERIAL PERCEPTIONS AND EXPECTATIONS

Cultural research in the organizational and managerial literature has focused on a plethora of managerial practices that differ across cultures. Many of these more applied findings have important contributions to psychological theory and research. In the next section, we highlight several key findings in this area, including cross-cultural research on attributions in the workplace, expectations of conflict, and beliefs about professionalism.

Cross-Cultural Attributions for Performance

Work is a domain where performance—success or failure—is of important consequence for both the individual and the organization, and attributions or explanations of performance have been a topic of extensive research in cultural workways. In this section we review three lines of research that have particular bearing on cultural psychology—positivity attributional biases, attributions to individuals versus groups, and organizational attributions.

Positivity Biases

How managers make attributions about positive and negative events such as success and

failure has important implications for the future performance of employees and the organization at large. For example, the propensity to make dispositional attributions to explain performance can lead managers to overlook important structural causes of failure (in the case of poor outcomes), or misappropriate resources to a few undeserving employees (in the case of good outcomes). The latter phenomenon was eloquently described by Malcolm Gladwell (2002) in his analysis of the downfall of the now infamous Enron Corporation. According to Gladwell, no expenses were spared to hire the best and brightest individuals from elite business schools during the heyday of Enron. These employees were fast-tracked and given huge financial and strategic responsibilities, even though they were underqualified, undertrained, and inexperienced. When these individuals failed, they were given more, rather than less, responsibility and control. Enron's culture of identifying a few winners, then maintaining their "star" status by consistently making dispositional attributions for their successes, while making situational attributions for their failures, contributed to the ultimate downfall of the entire company.

This propensity to focus on dispositional attributions of winners is consistent with cultural research on the positivity bias, or the propensity to make internal attributions for others' successes and external attributions for others' failures (the positivity bias is similar to the self-serving bias, except that the attributions are directed toward others; Sears, 1983). The Hallahan, Lee, and Herzog (1997) content analysis of how sports journalists make attributions about winners and losers found cultural variation in how the positivity attributional bias is expressed. Specifically, journalists from Western cultures predominantly focused on winners, making internal attributions for their successes, and praising their abilities to the sky. This results in a "star" culture in Western societies, where disproportionate attention is paid to the winners, and extraordinary and outstanding abilities and talents are attributed to them. Journalists from Eastern cultures, in contrast, predominantly focused on losers, making external attributions for their losses. In Eastern cultures, effort is expended on equalizing winners and losers, so that no one stands out—journalists spent more time making excuses for the losers, so that they did not appear below average or subpar.

Group versus Individual

Research has shown cultural differences in how individuals versus social collectives are held accountable for outcomes. Zemba, Young, and Morris (2005) found that Japanese were more likely than Americans to attribute organizational outcomes to a single leader (e.g., CEO). Specifically, they found that Japanese attributed blame to a business leader for harms caused by the organization (e.g., environmental accident), whereas Americans were reluctant to do so unless there was a clear connection between the action and the individual. Relatedly, Japanese leaders were more likely to take the blame and resign for organizational failure, it was not caused directly by their own actions and even if the cause originated before the leader became a member of the organization. Individual representatives of the group—such as the CEO or the leader—are viewed as the proxy of the group and have to assume blame for organizational level failures.

The notion that cultural differences exist in the status of groups and individuals also is salient in the literature on motivation. How to motivate workers to perform well or to exhibit other behaviors that the organization finds desirable is of great interest to business scholars and practitioners. The early work of William Ouchi (1981) showed that, in contrast to American managers, Japanese managers used the work team as the source for motivation for individual workers. Similarly, DeVoe and Iyengar (2004) showed that whereas American managers tend to attribute their subordinates' motivation exclusively to work-related incentives (e.g., salary), Latin American and Chinese managers are more likely to believe that social incentives (e.g., belonging to a group, building harmonious relationships) are more important sources of motivation for their subordinates. Like other research on cultural psychology, an individual's inextricable embeddedness within the social collective appears to be much more salient in Eastern than in Western cultures (Sagiv & Schwartz, 2000a).

Organizational Attributions

Besides individuals, social collectives such as organizations also make attributions. For example, several studies examined the attributions business organizations make for their performance by content analyzing the text in their

annual reports to shareholders (Bettman & Weitz, 1983; Lee, Peterson, & Tiedens, 2004; Salancik & Meindl, 1984; Staw, McKecheenie, & Puffer, 1983). Ambady, Shih, Hallahan, and Lee (2005) have used this technique to examine attributions across cultures. Specifically, they content-analyzed the attributions contained in the annual reports of publicly traded companies in four countries—India, Hong Kong, Singapore, and the United States. Results showed that Indian companies changed from a prototypical Eastern attributional style (more external attributions, or attributing performance to competitors, government policy, or economic conditions) before 1991—the year India experienced a large-scale economic restructuring to allow more Western capital—to a prototypical Western attributional style (more internal attributions, or attributing performance to managerial decisions or internal strategy) after 1991. During the same time period, attributions made by Singapore and U.S. companies (countries with no large-scale economic or political change during the 1991 time frame) showed no changes in their attributions. Also, attributions in Hong Kong companies changed from a prototypical Western attributional style before 1997—the year when Hong Kong was handed over to China from British rule—to a prototypical Eastern attributional style. Again, Singapore and U.S. companies showed no changes in attribution styles during the same time.

These results have several implications. First, they show that cultural differences in attribution styles are reflected in not only individual-level inferences of causality but also the publicly communicated inferences of social collectives. Although annual reports are written by individuals, they nevertheless represent the views of the business organization as a collective. The results show that, like individuals, organizational attributions reflect East–West differences in preference for internal versus external attributions. Second, cultural differences in organizational attributions are sensitive to larger cultural, political, and economic influences. Whether the observed attributional shifts in Indian and Hong Kong firms reflect changes in how the executives or employees of the organizations actually thought about their performance, or the organization's attempts at appealing to different audiences over time, they changed in predictable ways with larger “macro” forces in the economic and political environment, and the change occurred quite

quickly (a year after the seminal event). It appears that the cultural differences in organizational attributions are highly transitory and sensitive to the larger context.

Expectations about Conflict across Cultures

Research on conflict at work has most commonly focused on how different types of conflict affect individual and team performance. Although the data are somewhat equivocal, there is some evidence (primarily from U.S. and Northern European samples) that task conflict—disagreements about the work itself—can facilitate team performance and creativity through constructive debate (Jehn & Bendersky, 2003; DeDreu & Weingart, 2003). In contrast, relationship conflict—disagreements and dynamics unrelated to the task, which involve interpersonal tensions and personality clashes—is a robust and reliable predictor of team underperformance and dissatisfaction (DeDreu & Weingart, 2003).

However, expectations of and reactions to conflict do not mirror the empirical findings and further exhibit cultural differences. Neuman, Sanchez-Burks, Ybarra, and Goh (2005) conducted two studies comparing perceptions of task and relationship conflict among Americans, Koreans, Chinese, and Japanese managers. The results showed that both Americans and East Asians believed task conflict was a roadblock to success. Though East Asians also believed relationship conflict was detrimental to task performance, Americans did not believe that relationship conflict necessarily affected team performance. In fact, when given the opportunity to join a talented team that would likely experience relationship conflict, Americans were twice as likely as East Asians to state that they would join such a team.

Thus, there are both cultural differences and cultural similarities regarding beliefs about conflict: Americans share with other cultures the belief that task conflict limits team performance, but differ from other cultures in beliefs about the detrimental effects of relationship conflict on team performance. These findings are consistent with PRI, the uniquely American workway that minimizes the importance of social and emotional concerns at work; Americans expected work-related conflict to exact a toll on work performance but did not expect personal or social conflict to play a role at

work. This suggests that “conflict frames,” or subjective construals of conflict that influence decisions and behaviors (Gelfand et al., 2001, 2002; Pinkley, 1990), are more strongly shaped by prevailing cultural ideologies than by the actual relationship between conflict and performance.

Culturally Bound Beliefs about Professionalism

“Being professional,” in the vernacular of Western business speak, is an often-used standard invoked by organizations to regulate behavior of its members, or by individuals to manage others’ impressions using culturally and organizationally relevant cues such as décor or dress (Elsbach, 2003, 2004; Rafaeli & Dutton, 1997). Yet exactly what “being professional” means is rarely explicitly defined. Although idiosyncrasies may exist between industries, organizations, and even roles within a firm, notions such as professionalism can provide a window into culturally implicit meanings about how to behave appropriately while at work.

Recent research suggests that perceptions of professionalism are indeed culturally bound. Heaphy et al. (2007) assessed people’s schema of professionalism by having managers from multiple cultures affix images of work-related items (e.g., a stapler, file folder, or an award certificate) and non-work-related items (e.g., a family photo or a child’s drawing) to an image of an empty office cubicle of a person described as having either a “professional” or an “unprofessional” reputation. Results showed that perceptions of professionalism entailed restricting the amount of nonwork symbols to fewer than 20%. Interestingly, far from a cultural universal, this perception of professionalism was moderated by the amount of experience managers had working in the United States. Specifically, the more time managers had lived and worked in the United States, the more likely they were to perceive restriction of personal content displayed in the office as an indicator of high professionalism. Of course, all societies have beliefs about appropriate behavior at work. Though translations of professionalism appear in many cultures—*puro* in Japan, *epangelmatismos* in Greece, *profesionalismo* in Mexico—this research suggests that its particular connotations within American business are far from universal and, instead, are deeply imbued with tacit cultural meanings.

FUTURE DIRECTIONS

In this section, we highlight streams of research that may be particularly fruitful for the study of cultural workways in particular, and cultural psychology more generally. Particularly, we highlight theories, variables, and methodological approaches that are less common in psychological research but potentially provide a rich perspective for cultural psychology research in the future.

Social Networks

Cultural psychology of workways is not limited to a study of people’s minds or social contexts. Social networks, or the pattern of interconnections between individuals, play an important role in the mutual constitution of individuals and institutions within cultures (Morris, Poldony, & Ariel, 2000). Social network research examines actual patterns of social behavior—who talks with whom, whom people go to for task and personal advice, to whom people hand off their work—and the consequences of these various network strategies for individual, team, and organizational outcomes and behaviors.

Social network analysis offers much potential for future research in cultural psychology. For instance, multiplexity, or the degree of overlap in a social network, is a particularly interesting variable in that it taps both the content and the structure of the interconnecting web of people’s social relations. The level of multiplexity in individuals’ networks indicate the extent to which the same set of people serve multiple roles (e.g., the same person has the roles of confidant, coworker, and cousin simultaneously). For example, given the central PRI tenet of separating work and nonwork domains, the social networks of individuals in cultures influenced by PRI should have lower levels of multiplexity (Kacperczyk, Sanchez-Burks, & Baker, 2005).

Recent cross-cultural evidence supports this notion. Ariel et al. (2000) compared social networks among employees of a multinational bank in Spain, Germany, and the United States. They found that despite organizational attempts at standardization across its branches, there remained substantial cultural variations in actual patterns of social relations. For example, in Spain, employees’ networks showed greater multiplexity, that is, more overlap be-

tween advice and personal networks, such that the same person would be sought out for both work and personal advice. In contrast, American employee networks showed significantly lower multiplexity, indicating two nonoverlapping networks, one for work-related issues and one for personal issues.

Transitivity is another network characteristic that may be an important predictor for success within some Asian cultures (Gelfand & Cai, 2004). As mentioned, professional networks in China are fashioned in a way that is consistent with the broader notion of *guanxi*, in which two people who are connected based on mutual obligations can expect people in each other's networks to respond in kind despite being one step removed in the social network. For example, imagine Kaiping wishes a favor from a potential business associate, Chi-Ying, someone he does not know personally. Both Kaiping and Chi-Ying, however, are connected to a mutual friend Lijun. It is acceptable under the principle of *guanxi* for Kaiping to approach Chi-Ying directly, without going through Lijun. Kaiping can further expect Chi-Ying to offer him the same favors and special treatment she would offer to Lijun (Gelfand & Cai, 2004).

Understanding and adapting to social network characteristics such as multiplexity or transitivity may be a particularly critical skills for operating effectively in today's global marketplace. For example, having a network with a lot of multiplexity may be advantageous for a businessperson generating new business in Spain. Or having a highly transitive social network may benefit an entrepreneur who wishes to expand her business into China. In short, having network characteristics that fit in with another culture might facilitate one's success in operating within that culture.

The ability to alternate between multiple network strategies to "fit in" across multiple cultures may be an additional skill that predicts success in the global marketplace. For instance, businesspeople who have to work within multiple cultures might have to switch back and forth between a high-transitive and a low-transitive network, or a high-multiplex or a low-multiplex network, depending on their colleagues' cultural background. In this way, achieving "cultural fluency" may entail understanding and evoking different network structures across cultural divides.

Besides examining the relationship between various network characteristics and perfor-

mance across cultures, future research might also examine antecedents to culturally adaptive network structures and skills. For instance, prior exposure to different cultures might create more flexibility in network structures and strategies, such that multicultural individuals (who identify with different cultures) may have more facility in switching back and forth between different types of networks. Furthermore, network structures might powerfully affect individual belief systems. For example, the American entrepreneur who participates (willingly or not) in the Spanish business world and develops higher multiplexity in her social networks as a result might begin to attenuate her own beliefs about separation of work and nonwork life.

Organizational Culture

Cross-cultural research typically examines culture at the level of a nation (e.g., Japan vs. the United States) or the level of ethnic groups (e.g., Asian Americans vs. Latinos). Yet cross-cultural research also can be conducted at the level of the work group or work organization. "Organizational culture" refers to the observable values and norms that characterize an organization (Schein, 1996) or to commonly held schemas (ways of thinking about and doing things) that individuals within an organization might share. Organizational culture has been called a variety of terms, such as "organizational personality" (Barnard, 1968), corporate climate, corporate soul, or organizational psychounity (Denison, 1996).

In one sense, organizational culture is analogous to national or ethnic cultures (Alutto, 2002). Both types of "cultures" entail shared beliefs, values, and norms of a particular social system, be it a business organization or an entire society. One can think of organizations as nested in nations, where a country might have numerous organizations within it, and organizational cultures are influenced by the larger national culture in which they operate. Likewise, one can think of nations as nested in organizations—where multiple national units exist within a single organization (e.g., Hofstede's [1980] multinational study of IBM), and differences between national units are influenced by the larger organizational or firm culture.

Comparing these two research streams—organizational culture and national cultures—

side by side, it is evident that dimensions and concepts used to describe national cultures have been used to describe cultures within organizations or firms. For example, the concept of individualism–collectivism (INDCOL), originally used in cross-national comparisons, has been used to examine cultural differences between business firms, functional departments, or work teams within the same country (Lee, 1997, 1999). Particularly, multiple studies have examined how creating a more collectivistic versus individualistic orientation within a work group (via experimental manipulations) affects group and organizational dynamics (Chatman & Barsade, 1995; Lee, 1997, 1999).

Despite this limited cross-fertilization of the two literatures, little theory or research has explored the similarities and differences of cultures at these various levels of analysis. In an exception, Earley and Mosakowski (2002) suggest that, compared to organizations, national cultures are less transient and less affected by the entry and exit of any single individual. However, these differences have blurred as organizations have grown increasingly large, diverse, and global, whereas national values have been shown to be much more susceptible to environmental jolts and changes (Ambady et al., 2005).

Thus, one important direction for future research is examining the relationship between national cultures, organizational cultures, and individual psychology. One possible proposition is that organizational cultures may reflect the larger national culture in which they operate. For example, value differences that exist between cultures (i.e., autonomy–embeddedness, hierarchy–egalitarianism, mastery–harmony) may affect organizational cultures (Sagiv & Schwartz, 2000b). For example, organizations in autonomous cultures may be relatively open to change and diversity, but organizations in embedded cultures function as extended families, taking responsibility for organizational members in all domains of life. Organizations in hierarchical cultures may emphasize the chain of authority, assigning well-defined roles and goals to individual members, whereas organizations in egalitarian cultures may be more flexible in allowing individuals to decide how they will enhance organizational goals. Organizations in mastery cultures may be dynamic, competitive, and strongly oriented to achievement and success, whereas organizations in harmony cultures may be more con-

cerned with the organization's integration and impact on the larger society and environment.

Another possible proposition may focus on the interface between organizational and national cultures. Specifically, the fit between organizational and national culture may predict organizational performance. One may argue that organizations with cultures that fit in with the prevailing values of the larger national culture might be more successful, or more favorably perceived by shareholders and the general public. To the extent that organizations exhibit cultural values that are inconsistent with the larger culture, they may violate expectations held by the general public about what is generally good and desirable, leading to unfavorable impressions and lower stock prices (Lee et al., 2004). Alternatively, one may argue that organizations with cultures that differ from the prevailing values of the larger national culture will be viewed as more innovative and cutting edge.

Cultural Intelligence

Thinking is for doing and, within the domain of work, learning about culture is critical for successfully navigating cultural differences. The recent construct of cultural intelligence offers one such mechanism through which people can manage cross-cultural differences. Earley and Ang (2003) wondered why some people operate well in new cultures, while others have difficulty fully understanding or practicing new cultural values and behaviors. They suggested that this ability cannot be fully explained by social or emotional intelligence, empathy, or other individual differences. They coined the term “cultural intelligence” (or CQ) to describe an individual's ability to adapt to new and unfamiliar cultures. CQ has cognitive components (grasping culture-specific knowledge, as well as metacognitive skills such as self-awareness and ability to create new categories), motivational components (willingness to adapt and change oneself as the cultural context changes), and behavioral components (ability to generate new behaviors within a new cultural context).

As mentioned earlier, difficulty in managing cross-cultural business relationships is both common and costly (Copeland & Griggs, 1985), and many of these failures may be attributed to insufficient levels of CQ (Earley & Ang, 2003). CQ, though an individual difference, can indeed be developed. For

example, cognitions such as culture-specific knowledge—how to conduct a meeting in Japan or how to exchange gifts in China—can be learned, as can metacognitive skills relevant to CQ, such as social perception, reasoning, or self-monitoring. Similarly, motivation can be increased through goal-setting exercises to change individual attitudes. Behavioral change can be instilled through behavioral modification techniques.

CQ is a promising individual-level variable that directly addresses the concept of cultural fluency in intercultural interactions. Although CQ is applicable to most, if not all, dimensions along which cultures vary, future research may find that the usefulness of CQ is moderated by the nature of cross-cultural differences. For example, when individuals have to negotiate between cultural phenomena about which they do not have clear or intuitive understanding—for example, differences between high- and low-context cultures—CQ might prove especially helpful. Or when individuals are reluctant to admit to certain culturally ingrained behaviors due to self-presentation concerns, such as being less relationally attuned in certain settings, having high CQ or being trained in CQ might have a strong effect on improving the quality and effectiveness of intercultural contact.

Examining Cultures by Using Dilemmas

Dilemmas are an underutilized methodology for examining cultural differences. This approach is exemplified in the research of Hampden-Turner and Trompenaars (1993), who presented to respondents in multiple cultures a series of work-related dilemmas and asked them to make a choice between two extreme positions. For example, managers were asked to choose between the following descriptions of a company:

1. As a system designed to perform functions and tasks in an efficient way. People are hired to fulfill these functions with the help of machines and other equipment. They are paid for the tasks they perform.
2. As a group of people working together. The people have social relations with other people and with the organization. The functioning is dependent on these relations.

Using this approach, they found important cul-

tural differences and similarities specific to work, but with clear implications for broader contexts. For instance, in the aforementioned dilemma, only 36% of the managers from Japan chose (1), whereas this option was favored by 70% or more of the managers in the United States, with Sweden and Italy somewhere in between (56% and 46%, respectively). Hampden-Turner and Trompenaars argued that managers' decisions in such dilemmas reflect and express the national culture in which they operate—dimensions such as universalism, collectivism, and achievement.

Though some researchers (Oyserman, Coon, & Kimmelmeier, 2002) have questioned the validity of value dimensions such as INDCOL as a useful way to understand cultural differences, this criticism may reflect the problems with using scales as a way to measure values, rather than the concept of values per se. Indeed, Hampden-Turner and Trompenaars (1993) found that theoretically grounded dilemmas based on individualism and collectivism show consistent and theoretically explainable cross-cultural variation. This, together with the consensus with which other cultural theorists have described constructs analogous to INDCOL (e.g., Durkheim, 1933; Kluckhohn & Strodtbeck, 1961; Parsons et al., 1951; Reisman, 1961; Tönnies, 1887/2002), suggests that broad value dimensions could be usefully reexamined with the dilemma methodology in future research. Specifically, when the validity of self-reported values cannot be established (see Heine et al., 2002; Peng, Nisbett, & Wong, 1997), or when experimental methodologies are not viable (as in many applied field settings), the dilemma methodology exemplified in the research by Hampden-Turner and Trompenaars (1993) offers much promise.

CONCLUSION

The emerging research on cultural psychology and workways offers a unique perspective that is relevant for theory and research in cultural psychology. The interplay between the micro, psychological processes and the macro, structural processes that characterize the research on cultural workways provides critical insights for understanding how and why cross-cultural differences and similarities emerge, as well as when they may be particularly problematic for intercultural relations.

In understanding what constitutes a psychology of workways, it should be noted that much of experimental psychology may have unintentionally been studies on work. The most commonly used methodological paradigm in psychology experiments engages participants in a task-oriented “work” setting. For example, participants often come to an office and are asked to perform in some sort of problem-solving, decision-making, perceptual, or interpersonal task. Participants are typically given a set of instructions, and asked to follow them and perform accordingly within a given time frame. Also, participants typically receive some sort of compensation—money or course credit—for the “work” they perform.

Although participating in a short psychological experiment is clearly different than long-term employment within an organization or work group, participants in a typical psychology experiment are more likely to have a “working” mind-set than “playing” or social, nonworking mind-set, unless such a context is explicitly primed or created (e.g., studies of romantic partners). Findings from the experimental literature may therefore largely be studies of work-related cognitions, feelings, and behaviors. To the extent that a large part of cultural psychology employs this experimental paradigm, this may contribute to a cultural literature that overestimates the prevalence of certain types of cultural differences and underestimates other types of cultural differences. In this way, research on cultural workways provides a contextual anchor for assessing the cultural psychology of social life.

CHAPTER 15

Culture and Social Structure

The Relevance of Social Structure to Cultural Psychology

CARMI SCHOOLER

This chapter is written from the perspective of someone who functions professionally as not only a psychologist but also a sociologist. In fact, much of the chapter is written from a sociological perspective. This perspective is particularly germane for understanding the relevance of social structure—in brief, the arrangement of roles within a social system—to the concerns of cultural psychologists. Cultural psychology focuses on how one level of suprapersonal social phenomena—culture—affects the psychological functioning of the individual. It shares with much of psychology a distinct tendency to neglect the psychological effects of social structure. In doing so, cultural psychologists tend to treat all individuals in a culture as being subject to the same socio-environmental influences. This is definitely not the case. Dissimilarities in social-structural position, almost by definition, result in differences in the nature of the environment to which the individual is exposed.

The issue is not merely one of “independent” social-structural and cultural effects on psychological function. There is also the dis-

tinct possibility that culture and social structure may interact in affecting psychological functioning. Not only may cultural effects on psychological functioning vary among individuals in different social-structural positions, but the same social-structural position may also have different effects in different cultures.

In examining potential interactions between culture and social structure we should also consider the possible “reverse” effects of the psychological functioning of individual members of a society on its culture. As Cohen (2001) has noted, “Environmental circumstances lead to different cultural ‘traits’. Different ecologies . . . predispose a culture to different social structures” (p. 452). Particularly relevant to the question of the effects of social structure are cases in which psychological changes among individuals in various social-structural positions in a society—changes resulting from changes in that society’s socioeconomic structure (e.g., modes of production and distribution)—end up affecting its culture. Such effects of modes of production on the psychological

functioning and values of individuals in different social–structural positions within a society are among the principal social mechanisms underlying the hypotheses cited by Cohen (2001) as leading to differences in cultural values both across different societies and historically within a given society.

SOME DEFINITIONS

Before providing specific examples of these potential causal interconnections among culture, social structure, and psychological functioning, it is heuristically useful to define “culture” and “social structure,” as well as a series of related terms that help explicate their potential relationships. The definitions I present are adaptations and modifications of the general view of noted sociologist Robert Merton (1957a, 1957b) and well within the mainstream of sociological thought (for an extended discussion and elaboration of this theoretical framework, see Schooler, 1994).

- *Status*: A position in a social system occupied by designated actors (i.e., individuals or social organizations) that comprises a set of roles that define the incumbents’ expected patterns of interrelationships with incumbents of related statuses. Statuses may be ranked hierarchically in terms of the interrelated concepts of (1) prestige, (2) unequal distribution of relatively scarce social resources and unequal opportunity for acquiring them, and (3) power—the ability to induce others to fulfill one’s goals. When statuses are considered in terms of such a hierarchical perspective, the term “social status” is frequently used.

- *Social class*: The term “social class” is often used almost interchangeably with the term “social status.” Most sociologists who deal with stratification, however, distinguish between the two. They reserve use of the term “social class” to reflect the types of societal divisions envisaged by Marx. Thus, Kohn and Slomczynski (1990) describe social classes as “groups defined in terms of their relationship to ownership and control over the means of production, and their control over the labor power of others” (p. 2). I would amend this definition to include also ownership and control over the means of distribution. The focus of this review is on the more general concept—status.

- *Social structure*: The patterned interrelationships among a set of individual and organizational statuses, as defined by the nature of their interacting roles.

- *Culture*: A historically determined set of denotative (what is), normative (what should be), and stylistic (how done) beliefs shared by a group of individuals who have undergone a common historical experience and participate in an interrelated set of social structures. In a more expansive form, the definition could include the institutional, instrumental, and material embodiments of these beliefs.

- *Society or sociocultural system*: A set of persons and social positions that possesses both a culture and a social structure.

- *Caste*, the final term whose definition I present, is particularly germane to the issue of the relationship of social structure and culture, because it combines facets of both. In 1930, Kroeber defined a caste as “an endogenous and hereditary subdivision of an ethnic unit occupying a position of superior or inferior rank or social esteem in comparison with other such subdivisions” (p. 254). I would only add that castes “restrict the occupation of their members and their association with members of other castes . . . through social barriers sanctioned by custom, law or religion” (Lowe, McHenry, & Pease, 1985).

It should be noted that the definition of “culture” posits subordinate social structures. In turn, social structure is, by definition, posited to be superordinate to individual psychological functioning. These definitions thus presuppose that culture, social structure, and psychological functioning, although causally and ontologically related, represent different levels of phenomena (for a full discussion of emergent levels of reality based on the work and conceptualizations of the comparative animal psychologist T. Christian Schnierla [1951], see Schooler, 1994). Nevertheless, subordinate and superordinate levels of phenomena can affect each other. Thus, just as the characteristics of the superordinate cultural level may affect the characteristics of the subordinate social–structural level, the characteristics of the subordinate social–structural level can affect the superordinate cultural level.

Much more speculative is the possibility that among these levels of phenomena, superordinate levels tend to affect subordinate levels more quickly than the other way around. If so,

then psychological phenomena would more quickly be affected by social-structural phenomena than the reverse; in turn, social-structural phenomena, would be affected more quickly by cultural phenomena than the reverse. Empirically, such a possibility is suggested by a series of findings (e.g., Schooler, 1976; Kohn & Schooler, 1983; Schooler & Naoi, 1988; M. Naoi & Schooler, 1990) in which the effects of superordinate-level phenomena on subordinate-level phenomena are contemporaneous, whereas the effects of subordinate-level phenomena on superordinate-level phenomena are lagged (i.e., they occur over a longer period of time).¹

As elaborated by Schooler (1994), a possible theoretical explanation for such a temporal ordering starts with the truism:

Everything that exists has not been dysfunctional long enough or severely enough to cease being able to exist. From this perspective, the hypothesis about the different speeds at which things change can be reframed in terms of how long an element in a particular system can be dysfunctional before it ceases to exist, possibly by leading to the destruction of the system (e.g., organism, social structure, sociocultural system) of which it is a part. Thus, perhaps, because less redundancy is likely to exist at subordinate than at superordinate levels, the lower the level of phenomena, the shorter the period for which it can tolerate dysfunctional elements. . . . If more complex levels tend to have a greater degree of redundancy, a greater number of dysfunctional elements would be necessary to disrupt them. . . . Dysfunctional elements in a person's thought processes are likely to threaten the thinker's existence more quickly than dysfunctional elements in a social structure are likely to lead to the end of the social structure. In a similar manner, cultural level phenomena may be more resistant to change than social structural level phenomena because phenomena at the sociocultural system level are superordinate to those at the social structural level: not only are social structures elements of cultural level phenomena, but cultural beliefs affect the role expectations that pattern social structures. (p. 268; Schooler, 1994, contains a more extended discussion of the theory)

Leaving aside the question of the exact mechanisms through which such effects occur, social structures are obviously affected by what happened in their past. Thus, social structures are influenced by past history, just as are cultures. For our present purposes, the important

distinction, is that, as noted earlier, a society's culture seems apt to change more slowly than its social structure. Cultures tend to remain affected by events in the relatively distant past, including such specific ones as which side holding which ideology won what battle, or which unusual person with what abilities and beliefs appeared when. A society's social structure, on the other hand, is affected by not only its historically determined culture but also by relatively immediate exigencies such as its socioeconomic processes of production and distribution (Schooler, 1996). It is at least in part to take into account this possibility that, as a matter of emphasis, the term "historically determined" is included in the definition of culture, but not in the definition of social structure.

Whether or not there actually is a consistent difference between the speeds with which culture, social structure, and individual psychological functioning generally affect each other, it is clear that these three levels of phenomena do affect each other. In the next several sections I provide examples of such effects that are pertinent to the issue of the relevance of social structure to cultural psychology. I begin by supplying evidence of the direct relevance of social structure to the study of the psychology of the individual by presenting three illustrative examples in which social structure directly affects psychological functioning: (1) the psychological effects of occupational conditions; (2) the interconnections of social structure, stress, and mental and physical health; and (3) the effects of social structure on the psychological determinants of educational outcomes.

Because this cultural psychology handbook is replete with instances in which culture affects individual psychological functioning, I omit parallel examples demonstrating such cultural effects. Instead, I devote the bulk of the review to illustrating and discussing how the effects of culture and social structure often interact in affecting psychological functioning. As a consequence of such interactions, it is often necessary to take into account culture and social structure simultaneously if we are to understand the effects of each. I conclude my literature review by discussing several examples of how cultural and social-structural factors interrelate in affecting how caste membership influences psychological functioning—with caste itself representing a dense interweaving of cultural and social-structural elements.

EFFECTS OF SOCIAL STRUCTURE ON PSYCHOLOGICAL FUNCTIONING

Central to my discussion of the effects of social structure on psychological functioning is the hypothesis that social-structural differences in the complexity of the environments, particularly work environments, faced by individuals in different positions in a society's social structure play an important part in accounting for social status differences in levels of intellectual functioning and self-directed orientations and values in that society. My reasoning centers on a rough-hewn theory of the psychological processes through which complex environments have their effects (Schooler, 1984, 1990a). According to this theory, the complexity of an individual's environment is defined by its stimulus and demand characteristics. The more diverse the stimuli, the greater the number of decisions required, the greater the number of considerations to be taken into account in making these decisions, and the more ill defined and apparently contradictory the contingencies, the more complex the environment. Such environments put a premium on intellectual flexibility—the ability to use an assortment of approaches and vantage points in confronting cognitive problems in a non-stereotypical way. To the degree that such an environment rewards cognitive effort, individuals should be motivated to develop their intellectual capacities and to generalize the resulting cognitive processes to other situations. Conversely, continued exposure to relatively simple environments may have the opposite effects. The theory is consistent with findings of a large body of research from a wide range of disciplines, including animal-based neurobiology (e.g., Kempermann, Kuhn, & Gage, 1997; Greenough, Cohen, & Juraska, 1999), indicating that exposure to complex environments increases intellectual functioning throughout the life course and across species (Schooler, 1984, 1990a, 2007). I define intellectual functioning by the level of complexity of the problems that the individual is currently able to solve.

Nonintellectual aspects of psychological functioning should also be affected by environmental complexity. To the extent that complex environments reward initiative and independent judgment, such environments should foster a generalized orientation to self-directedness rather than conformity to external authority. It is also plausible that experience in

complex environments leads to the development of a kind of subjectivism deriving from both the feeling that locus of control is and should be within oneself and the importance given to mental processes by the emphasis placed on effective cognitive functioning (Schooler, 1972).

The hypothesis about the positive effects of doing self-directed substantively complex work on intellectual functioning provides a clue to, at least, a partial explanation of what has been termed the "Flynn effect" (Neisser, 1998)—the trend in industrial societies, ever since testing began, for scores over a wide range of intelligence tests to rise by about 3 IQ points per decade (Flynn, 1987). If technical and economic development leads to more complex environments and to more intellectually demanding work conditions, such increased environmental complexity should result in higher levels of intellectual functioning. Such an increase in environmental complexity almost certainly occurred in the move from rural to urban settings, and from premodern agricultural to commercial and manufacturing occupations. There is also evidence that the substantive complexity of work continues to increase at later levels of development (Attwell, 1987; Dickens & Flynn, 2001; Form, 1987; Penn, Michael, Rose, & Rubery, 1994). Given this increasing complexity of work demands and other aspects of life, and the causal link between levels of environmental complexity and intellectual functioning, the ongoing gains in intelligence test performance that Flynn (1987) found can be seen as due, in some large part, to the way the world has become more complex. For a full discussion of the plausibility of this view of the Flynn effect, see Schooler (1998).

More generally, the complexity of the intellectual demands made by modern occupational and other social conditions can also be seen as contributing to what have been described as the psychological consequences of modernization. The pioneer quantitative, cross-national study examining the psychological correlates of modernization was the Project on the Sociocultural Aspects of Development. Led by Alex Inkeles, its goal was to test his hypothesis "that the standardized institutional environments of modern society induce standard patterns of response, despite the countervailing randomizing effects of persisting traditional patterns of culture" (Inkeles, 1960, p. 1). It did so by examining the degree to which individu-

als “incorporate as personal attributes qualities which are analogous to or derive from the organizational properties of the institutions and roles in which . . . [they] are regularly and deeply involved” (Inkeles, 1983, p. 8). Tying this question specifically to modern experience, Inkeles and Smith (1974) selected the factory as an embodiment of many aspects of such experience. From an analysis of factory characteristics they derived a set of qualities that they assumed would be learned and incorporated as personal attributes by men who experienced extended factory employment after growing up in a premodern rural village. This set of qualities, which they called *individual modernity*, consisted of openness to new experience, independence from traditional authority, belief in science and medicine for solving human problems, educational and occupational ambition, punctuality and orderliness, and interest in civic affairs (Inkeles, 1969).

The research was conducted in six industrializing nations—Argentina, Bangladesh, Chile, India, Israel and Nigeria; almost 6,000 men served as survey respondents. Analyses of the data indicated that the various hypothesized aspects of modernity, do, in fact, co-occur in a syndrome of individual modernity. Furthermore, the findings demonstrated robust cross-national empirical relationships between the various psychological aspects of individual modernity and work in industrial settings, as well as exposure to such other concomitants of modernization as urbanization, education and mass media. In each of the countries studied, exposure to social-structural conditions associated with industrialization was generally shown to be empirically correlated with the psychological characteristics predicted by the Project’s theory.

Despite the strength of its empirical findings, the Project has been criticized for a variety of ideological reasons. For example, from the neo-Marxist perspective, Wallerstein (1974) has characterized it as an apologia for the capitalistic, imperialistic status quo. Somewhat similarly, from the postmodernist perspective, Luke (1991) sees the modernity thesis as a “dehistoricized, desocialized and deculturalized-social theory” (p. 284) that the power elite uses as a legitimating ideology to control the masses socially.

Despite these ideological complaints, there does not seem to have been any major study that refutes the original Inkeles and Smith (1974) empirical conclusions. In fact, Inglehart

and Baker’s (2000) reanalysis of an extensive series of cross-national surveys in terms of traditional values versus secular–rational values and survival versus self-expression values strongly attests to the general validity of Inkeles et al.’s general findings about the psychological effects of modernization. Thus, Inglehart and Baker conclude that although “the broad cultural heritage of a society—Protestant, Roman Catholic, Orthodox, Confucian or Communist—leaves an imprint on values that endures despite modernization . . . economic development is associated with shifts away from absolute norms and values towards values that are increasingly rationale, tolerant, trusting and participatory” (p. 19). A complaint that can be legitimately raised about Inkeles and his colleagues is their conceptual and empirical ambiguity about how the socioenvironmental conditions and psychological characteristics they associate with modernity relate to each other. Although Inkeles and his associates (Inkeles, 1983; Inkeles & Smith, 1974) described several mechanisms through which such changes may take place (i.e., reward and punishment, modeling, exemplification, and generalization), they never empirically isolate which aspects of the modernization experience have these effects.

Psychological Effects of Occupational Conditions

The attempt to specify how the social-structurally determined environmental conditions that individuals face in modern societies affect their psychological functioning was an underlying aim of the project on the psychological effects of occupational conditions that Melvin Kohn and I originally conceived in the early 1960s. The initial impetus of the study was to test the hypothesis that social status differences in occupational conditions were the cause of the social status differences in parental values that Kohn (1959) had previously found. In the course of developing our research protocol, our goals expanded greatly. The general purpose of the study became to test the hypothesis that social status differences in people’s orientations toward themselves and their environments, in the values they hold for themselves and their children, and even in the ways that they think, are a function of the nature and conditions of their work.

To delineate the exact linkages between individuals’ conditions of work and their psycho-

logical characteristics, we did not compare specific jobs; rather, we conceived of a job in terms of a series of dimensions. Among these were substantive complexity, closeness of supervision, routinization (seen as indicative of occupational self-direction), ownership, bureaucratization, position in the hierarchy, and time pressure. Substantive complexity was the keystone concept in regard to occupational self-direction, in terms of both our theoretical perspective and empirical findings. We defined “substantively complex work” as work that in its very substance requires thought and independent judgment (Kohn & Schooler, 1983, p. 106). Indices for the latent concept of substantive complexity of work are derived from detailed open- and closed-ended questions about the participants’ work with things, data (or ideas), and people. The questions provide the basis for seven ratings: appraisals of the complexity of each respondent’s reported work with things, with data, and with people based on those of the *Dictionary of Occupational Titles* (U.S. Department of Labor, 1965), as well as respondents’ estimates of the amount of time they spent working at each type of activity.

The original sample of 3,101 men interviewed in 1964 was representative of all men in the United States employed in civilian occupations. In a 1974 follow-up, a representative subsample of those men, who were then under 65 years old, was reinterviewed, and their wives and children were interviewed for the first time. Analyzing the men’s longitudinal data with the then newly developed technique of structural equation modeling (SEM; Joreskog, 1973), we found that jobs that facilitate occupational self-direction, increase intellectual functioning, and promote a self-directed orientation to self and to society (Kohn & Schooler, 1983).² Further findings demonstrated that opportunities for exercising occupational self-direction are to a large extent determined by a job’s location in the social structure of society. Other results indicated that oppressive working conditions produce a sense of distress. In all of these findings there is the consistent implication that the principal process by which occupations affect personality is generalization from the lessons of the job to life off the job. Interviews with the male respondents’ wives revealed a similar pattern of psychological effects of occupational conditions among employed women (J. Miller, Schooler, Kohn, & Miller, 1979).

In 1994, I and my colleagues in the National Institute of Mental Health (NIMH) Section on Socioenvironmental Studies carried out a 20-year follow-up survey on the surviving members of the adult 1974 sample. Our findings, (Schooler, Mulatu, & Oates, 1999, 2004) are based on the 166 men and 78 women who were working when interviewed, both times that they were surveyed. These findings replicate and extend the earlier Kohn and Schooler (1983) findings about the effects of substantively complex self-directed work on intellectual functioning, and self-directed values and orientations when the sample was 20 years younger. Our new findings provide consistent, credibly strong evidence that even in old age, carrying out self-directed, complex tasks on the job has a positive effect on intellectual processes and also increases self-directed orientations. Because each of these general psychological characteristics is both caused by and causes high social status, our findings also confirm and elucidate the complex causal patterns through which social status, occupational conditions, and psychological functioning affect each other (Schooler et al., 2004).

From the very beginning, Kohn and I realized that cross-national replication represented one of the best ways to test the generalizability of our hypotheses. In fact, the first cross-national attempt to test these hypotheses (Pearlin & Kohn, 1966) was actually carried out in Turin well before the analysis of the data from the original 1964 U.S. survey was completed. Consequently, its indices, particularly for occupational self-direction, are only approximate. Still, the Turin study was the first to provide evidence that the relationship between social stratification and fathers’ valuation of self-direction for children is substantially attributable to occupational self-direction. The study even provided evidence that the relationship between the men’s social stratification position and their wives’ values is in part attributable to the men’s job conditions.

The cross-national replications methodologically closest to the Kohn–Schooler U.S. NIMH studies were carried in Poland and Japan, in direct collaboration with the NIMH investigators. The major purpose of these collaborations was to ascertain whether social–structural position has similar psychological effects in a Western and a non-Western, and in a capitalist and a noncapitalist, society. Finding similarities among these three countries in the psychologi-

cal effects of being in an advantageous social-structural position and in the importance of occupational self-direction in explaining these effects, would provide considerable evidence that our findings have cross-cultural generality.

The Polish survey, directed by Kazimierz Slomczynski, was conducted in 1978 with the collaboration of Melvin Kohn (see Kohn & Slomczynski, 1990, for the most complete English description). The probability sample of 1,557 men was representative of men living in urban areas and employed full time in civilian occupations. The study was designed to be an exact replication of the main parts of the Kohn-Schooler study. Questions about occupational self-direction and psychological functioning were adopted from the Kohn-Schooler interview schedule. Overall, the Polish replication provided very strong confirmation of the Kohn-Schooler hypotheses. The findings

demonstrate that occupational self-direction plays the pivotal role in explaining both the effects of social structure on personality and the effects of personality on achieved position in the social structure. Position in the class structure and in the stratification order affect men's values, intellectual flexibility and self-directedness of orientation primarily *because* they affect occupational self-direction; occupational self-direction, in turn, affects these facets of psychological functioning. These facets of psychological functioning affect men's positions in the social structure mainly *because* they affect occupational self-direction, which then affects class placement and status achievement. (Kohn & Slomczynski, 1990, p. 170)

Analyses of a replication carried out in Poland in 1992 and a companion study carried out in the Ukraine in 1993 (Kohn et al., 1995) indicate that radical social change does not change the pattern of relationships between social structure and personality found under stable social conditions. Instead, radical social change transforms social structures. In the process of transformation, the social structures of Poland and Ukraine increasingly resembled the social structures of the more capitalist types of society. By late 1992, Poland exhibited the capitalist pattern and early in 1993, Ukraine was not far behind (Kohn et al., 1997). The individuals in these societies changed as their social statuses changed—evidence that the psychological functioning of the individual is quite sensitive to social-structural change.

The Japanese replication was carried out by researchers at Tokyo and Osaka Universities under the direction of Atsushi Naoi, with my collaboration. The interview consisted primarily of questions translated from the original Kohn-Schooler U.S. survey. The 629 male respondents were drawn from a random probability sample of employed males, 26–65 years old. The results indicated that advantageous social-structural positions are related to parental valuation of self-direction, to intellectual flexibility, and to self-directedness of orientation for Japan very much as they are for the United States and Poland. Occupational self-direction has the same psychological effects and plays precisely the same role in explaining the relationships of social-structural position and personality for Japan as it does for the United States and Poland (A. Naoi & Schooler, 1985). These findings hold true even when traditionality of job settings and economic centrality of industry are statistically controlled (Schooler & Naoi, 1988).

As was the case in the United States, a similar pattern of psychological effects of occupational self-direction was found when the employed wives ($N = 246$) of the sampled Japanese men were interviewed (M. Naoi & Schooler, 1990). Because one of the most consistent themes in accounts of Japanese culture is the deemphasis of individualism and the importance placed on psychological interdependence (A. Naoi & Schooler, 1985), finding that occupational self-direction has the same effects in Japan as in the more individualistically oriented United States represents a very real increase in the generalizability of our hypotheses about the effects of occupational conditions.

Social Structure, Stress, and Mental and Physical Health

There is an extensive literature examining the interrelationships among social structure, stress, and mental and physical health. The most general findings are that relatively poor social-structural position is related to relatively high levels of stress (e.g., McLeod & Kessler, 1990; Stansfield, Head, & Marmot, 1998) and relatively poor mental health (Marmot, Ryff, Bumpass, Shipley, & Marks, 1997) and physical health (Adler, Marmot, McEwan, & Stewart, 1999). Intriguingly, the impact of social structure on health is not merely at the poverty line. The relationship is so regularly linear that

it has been described as a gradient in which health status apparently improves with every increment of socioeconomic status (SES; Adler & Ostrove, 1999; Marmot, 1999). SEM analyses of the data from our 1974–1994 longitudinal survey confirmed that “a notable part of the effect of SES on health is due to psychological distress” (Mulatu & Schooler, 2002, p. 22).

Gallo and Matthews (2003) provide a full and excellent review of the relevant research literature on the role of negative emotions in the association between SES and health. They conclude by presenting “a general framework for understanding the roles of cognitive emotional factors, suggesting that low SES environments are stressful and reduce individuals’ reserve capacity to manage stress, thereby increasing vulnerability to negative emotions and cognitions” (p. 10). As this framework implies, “studies that account for initial differences in stress exposure suggest that at every level of stress, individuals with low SES report more emotional distress than those with higher SES” (p. 34). Thus, social–structural position affects not only the amount of stress to which an individual is exposed but also the ability of that individual to deal with the resultant stress level.

Social Structure and Educational Outcomes

There is ample evidence that social structure affects educational outcomes. From kindergarten on, those from families relatively high in social status do better in school and go further up the educational ladder than those from less privileged social origins. The social–structural differences in level of schooling are not merely reflections of possible differences in mental ability that may derive from some combination of genetic and environmental factors. Also involved are social–structurally based differences in self-directedness and self-regulation, aspirations, perceptions of others’ views of oneself, and actual and perceived resources.

Much of the best research in this area has been carried out by the Wisconsin Longitudinal Study of Social and Psychological Factors in Aspirations and Achievements (for a summary, see Sewell, Hauser, Springer, & Hauser 2001). The original data collection for this study was based on a 1957 survey of the postsecondary educational plans of all high school seniors in the public, private, and parochial schools of Wisconsin. Follow-up surveys that included

not only a representative subsample of the original respondents but also their siblings and spouses were carried out in 1975–1977, 1992–1994, and 2002–2003. Throughout, the analyses have been carried out by some of the most sophisticated data analysts in the social sciences. In terms of educational aspirations, the Wisconsin researchers found that “for each gender, socioeconomic status is a powerful determinant of who will plan on college—even when intelligence measured is controlled” (Sewell et al., 2001, p. 8). Furthermore, it is the children’s “perceptions of their parents’ intent to encourage their educational aspirations that is crucial to the development and maintenance of those aspirations. . . . The educational attainments of both parents has strong positive effects on the aspirations of their children” (Sewell et al., 2001, p. 9).

In terms of actual academic attainment, Sewell et al. (2001) report that “when academic ability was controlled by dividing the sample into quarters according to the students’ measured cognitive ability, we still found that higher socioeconomic status students attained substantially higher educations than did lower status student” (p. 13). A high-ability student coming from a family of high SES was approximately 3.5 times more likely to obtain a graduate degree or professional education than a student with similar cognitive ability who came from a family with low SES.

Sewell et al. (2001) concluded that “perhaps the most interesting finding was that educational aspiration strongly affected educational attainment, independent of its relationship to measured intelligence and socioeconomic status” (p. 14). Thus, educational attainment was strongly affected by a psychological characteristic—individuals’ educational aspirations—that had been strongly affected by their perceptions of their parents’ educational expectations for them. These perceptions were in turn affected by their families’ positions in the social structures of their societies. This pattern of findings provides an example of how psychological characteristics, even noncognitive ones that are affected by a family’s position in the social structure of its society, may decrease the likelihood of intergenerational mobility and thus increase the likelihood of reproduction of social status across generations.

The consequences for school performance of the effects of social structure on children’s psychological functioning manifest themselves at

the very beginning of the school career. Here too, such social structural differences are not limited to possible differences in intellectual functioning. As we have seen, the original impetus of the Kohn–Schooler occupation studies was to substantiate earlier findings that higher status parents were more likely than lower status parents to have values for their children that emphasized self-directedness rather than conformity, and to link these differences to disparities in the job demands of high- and low-status occupations (Kohn & Schooler, 1983).

Whether or not the SES differences in parental values are responsible for SES differences in childrens' self-regulation, such differences in self-regulation appear to exist and appear to predict school adjustment. Convincing evidence that this is the case is provided by Miech, Essex, and Goldsmith (2001) in a study using longitudinal data from 451 mothers in the Wisconsin Study of Family and Work. The mothers' survey included questions assessing their children's levels of self-regulation before they entered kindergarten. The kindergarten teachers assessed the children's: (1) overall problems in interpersonal relationships in school, (2) hyperactivity–attention deficiency, and (3) present and future academic ability. Miech et al. found that “self-regulation served as a mediator of the association between children's SES and both interpersonal problems at school and teachers' expectations” (p. 102). For example, after the influence of self-regulation was controlled, “the association between SES and relationship difficulties was diminished by 39 percent and was not statistically significant” (p. 108).

A source of unease among educators is the possibility that students may lose some of the skills and knowledge that they have acquired during the school year over summer vacation. Of particular concern has been the possibility raised by evidence collected in past decades that such loss was greater among children coming from lower SES families (e.g., Heyns, 1978; Entwisle, Alexander, & Olsen, 1997). These earlier studies did not take into account the timing of the pre- and postvacation tests during the school year. By not doing so, they left open the possibility that at least part of the differences found were due to social background differences in rates of learning while schools are in session. Recent analyses of data from a nationally representative U.S. sample (Burkam, Ready, Lee, & LoGerfo, 2004) have found that

even when time of testing is taken into account, students from different SES levels differ in what happens to their skills during the period between kindergarten and first grade. When the students are divided into quintiles in terms of their family SES, those from higher SES backgrounds continue to learn during the summer, whereas those from lower SES backgrounds lose some of the knowledge and abilities that they have learned. For reading, these differences follow a linear trend across SES quintiles. For mathematics and general knowledge the differences are not strictly linear: The lowest SES quintile loses knowledge and ability during vacation; the upper SES quintile gains knowledge, whereas the knowledge levels of the middle three quintiles remain the same.

There has been a strong suspicion (e.g., Entwisle et al., 1997) that such SES differences in the cognitive effects of vacations may be due to SES differences in the intellectual content and stimulation of the environments to which children are exposed when they are not in school. Burkam et al.'s (2004) analyses do not provide strong support for such a contention. They admit, however, that their measures may not adequately assess the relevant environmental characteristics. Nevertheless, whatever the exact causal mechanisms, Burkam et al.'s analyses provide a compelling example of the psychological effects of individuals' positions in the social structure of their societies—effects that influence individuals' abilities to take full advantage of the opportunities that their societies provide.

The Importance of Social Structure

In this section I have provided evidence that individuals' positions in the social structures of their societies can vitally affect them. We have seen how social–structural position can affect intellectual functioning and orientations to oneself and to others. We have seen how it can affect health, the level of stress to which individuals are exposed, their ability to cope with this stress, and their physical and mental health. The presented evidence shows that the effects of social–structural position extend beyond individuals to their families. This evidence demonstrates that parents' social–structural positions affect the school performance and educational attainment of their children—not only in terms of intellectual functioning but even when the level of their

children's intellectual functioning is controlled.

The evidence that I have presented is only a selection from the vast amount of evidence that attests to the importance to individuals of their positions in the social structures of their societies. Underlying all of this evidence is the general principle that advantaged position in the social structure of, at least modern industrial and postindustrial societies, does not merely result in economic advantage (financial capital). Such favored positions also result in gains in human capital (peoples' skills and abilities as used in employment), social capital (the social network of the individual's family, friends, acquaintances, and contacts), and cultural capital (social status-linked cultural tastes, knowledge, and abilities). These forms of capital, although different, have the distinct possibility of converting into each other, so that a gain (or loss) in one form of capital can result in gains (or losses) in the others. It is just such ramifications of the effects of social status that make it so important for cultural, and other, psychologists to keep social structure in mind as they pursue their research and develop their theories.

SOME EXAMPLES OF THE INTERACTION OF SOCIAL STRUCTURE AND CULTURE IN AFFECTING PSYCHOLOGICAL FUNCTIONING

Cross-national studies testing hypotheses about the psychological effects of occupational conditions have come up with a variety of findings that involve interactions between a society's cultural characteristics and the ways that society's social structure affects the psychological functioning of its members. Thus, although both the Polish and the Japanese replications confirmed the cross-national generalizability of the Kohn-Schooler hypotheses, both studies provided intriguing evidence of how a nation's culture can also affect the ways conditions of work affect the individual psychologically.

The cross-national discrepancies between Polish and U.S. findings tend to center around cultural differences in attitudes toward authority (Kohn & Slomczynski, 1990). Thus, in the United States, the substantive complexity of work is generally the most important aspect of occupational self-direction for explaining the impact of social structure. In Poland, closeness of supervision is relatively more important and has its primary psychological impact through

its effect on authoritarianism-conservatism. The positive correlation of closeness of supervision with authoritarianism-conservatism is notably higher there than in the United States. Kohn and Slomczynski see this higher correlation "as reflecting the greater saliency of authority in Polish than in American society. . . . It was in the self-interest of both the state bureaucracy and the church to support those elements of traditional Polish culture that encourage people to obey all forms of authority" (p. 207).

Another cross-national difference that Kohn and Slomczynski (1990) see as reflecting the greater cultural acceptance of traditional modes of authority in Poland compared to the United States is in the relative roles of fathers and mothers in the intergenerational transmission of values. In the United States, fathers tend to play a relatively important role; in Poland, mothers play the predominant role. Kohn and Slomczynski (1990) do not attribute this cross-national discrepancy to differing economic and political systems in the two countries. Rather they "think it is a historically rooted cultural contrast: Polish fathers play a more traditional role than do US fathers in the division of labor within the family and in the socialization of children. . . . The traditional Polish pattern where mothers have primary responsibility for child rearing and fathers' roles in the socialization of children focus on control and punishment, still obtains in many families" (p. 208).

When we examine Japan, we find that most of the cross-national differences relate to the nature and pervasiveness of the psychological effects of organizational position. The pattern of findings provides support for those who emphasize the general psychological importance of the group to the individual in Japanese culture and the specific importance to the Japanese worker of the organization for which he or she works (A. Naoi & Schooler, 1985), as well as for those who stress the cultural importance of hierarchical position (Nakane, 1970). In Japan, ownership and high position in the work hierarchy increase self-confidence and decrease self-deprecation. These job characteristics have no such effects in the United States (Kohn & Schooler, 1983) and may actually have had the opposite effects in socialist Poland (Kohn & Slomczynski, 1990). In Japan, as opposed to the United States and Poland, ownership and high hierarchical position at work lead to greater authoritarian-conservatism.

High hierarchical level at work also leads to more idea conformity and less personally responsible standards of morality. The scale measuring authoritarian-conservatism in Japan is actually marked by a higher degree of obeisance and respect for authority than its counterpart in the United States. The greater authoritarian-conservatism of Japanese in favorable organizational positions may reflect culturally embedded attitudes. Because of the “strong tendency for consequential human relations to have a vertical structure” in accord with Japanese cultural values (Caudill, 1973, p. 249; Nakane, 1970), Japanese in authority may tend to believe that such obeisance is appropriate, that moral principles can be bent to their needs, and that others share these beliefs.

Japan also provides an example of how cultural inertia may slow down social-structural and, consequently, psychological change. The evidence is strong that self-directedness is valued even less for women than for men in Japanese culture (Lebra, 1984; Schooler & Smith, 1978). It is highly plausible that this difference fosters the social-structural differences we find when we compare job roles of Japanese men and their wives (M. Naoi & Schooler, 1990). The wives’ jobs are significantly lower in every component of occupational self-direction. Thus, Japanese cultural norms increase the likelihood that women will work in generally subservient, non-self-directed, low-prestige positions. As we have seen, occupying such positions reduces the self-directedness of their orientations. This would increase the likelihood that they will remain amenable to the cultural norms devaluing women’s autonomy (which, of course, played a part in their original discriminatory occupational placement) and decrease their motivation to organize in defense of women’s rights. It will be interesting to see what may happen as a result of the recent trend for Japanese women to attain higher status jobs. There is evidence (Faiola, 2004) that this trend may result in a lesser willingness to get involved in “traditional” marriages with Japanese men—marriages that even a quarter of a century ago were often characterized by a psychological disengagement of Japanese wives from their husbands (Schooler & Smith, 1978).

Individuals’ orientations toward themselves and others are affected by not only interactions between culture and social structure, as reflected by occupational position but also by

interactions between culture and social-structural position, as embodied in education. Authoritarianism represents a striking example of such an interaction between culture and education. A substantial body of research links relatively favorable social-structural position with nonauthoritarian, generally self-directed orientations (for a review of the literature, see Farnen & Meleon, 2002). As indicated by the studies of the psychological effects of occupational conditions described above, much of this relationship may be due to the greater level of occupational self-direction that generally characterizes occupations well situated within the social structures of the relevant societies. Nevertheless, as we have seen in the case of Japan, a society’s cultural values may influence the strength of the relationship between favorable social-structural occupational positions and self-directed orientations, sometimes doing so to the extent that it is reversed. Similarly, although there is a general tendency for education, which is typically an important indicator of both adult social status and social status of origin, to be linked to nonauthoritarian, self-directed orientations, there are a more than a few instances in which cultural values affect the strength of the relationship.

Simpson (1972) examined the relationship between education and authoritarianism in four societies. In the United States and Finland, he found the strong, expected relationship. In Costa Rica, education reduced authoritarianism only after the eighth grade. In Mexico, education had little effect on authoritarianism. Simpson hypothesized that “education will reduce authoritarianism only when the educational system emphasizes cognitive rather than rote learning or is manned by non-authoritarian teachers” (p. 223). Duckitt (1992), who retested this hypothesis in a study that dealt with several potential concerns about the Simpson study, used an established measure of authoritarianism (Ray, 1979) whose items were balanced in terms of whether agreement or disagreement was indicative of authoritarianism. He dealt with the issue of whether Simpson’s findings might result from non-educational socioeconomic differences between the countries by comparing English- and Afrikaans-speaking white South Africans; although the two groups are generally matched on socioeconomic dimensions, Afrikaans culture is generally viewed as more authoritarian. Duckitt concluded that

the findings for English speaking White South Africans were consistent with a considerable amount of research indicating that increasing levels of formal education are associated with lower levels of authoritarianism . . . but the findings for Afrikaans speakers were not. The results of this study support Simpson's (1972) earlier observation that the relationship between education and authoritarianism may not be invariant and that, in certain sociocultural contexts, it will be severely attenuated or even absent. (p. 706)

In further support of this conclusion it is worth noting that Kohn and Slomczynski (1990) found no direct relationship between levels of authoritarianism and years of schooling in the Polish educational system—a system that may well have been characterized by authoritarian teachers and curricula.

In a more wide-ranging analysis based on representative data from over 40 countries, Farnen and Meleon (2002) found that the correlation between education and authoritarianism was substantially lower among states that had a history of totalitarian rule compared to those who had no history (−.22 vs. −.30). A similar pattern of correlations was found when states that were rated high on a state authoritarianism scale were compared to those rated medium and low on that scale (−.33 vs. −.26 vs. −.17.). Interestingly, when Farnen and Meleon compared the correlation between education and authoritarianism among economically developed, developing, and undeveloped countries, the size of the negative correlation decreased as the level of economic development decreased (−.33 vs. −.25 vs. −.15). Unfortunately, Farnen and Meleon did not carry out any analyses that simultaneously examined the effects of a history of totalitarian rule, high state authoritarianism, and economic development, so that we cannot know how much each of these cultural and socioeconomic factors independently affected the correlation, or whether they may have interacted in doing so.

It is also the case that what may initially appear to be culturally determined cross-national differences in interactions between cultural and social-structural variables may be the result of cross-national economic differences. Kunovich (2004) used hierarchical linear modeling to analyze multilevel data from 17 East and West European countries. He found that at the overall individual level, education and income reduced prejudice, and that prejudice increased when the individual occupied a labor market

position likely to involve direct competition with immigrants. When, however, he compared the magnitude of these effects in the different countries, he found that these effects “are weaker in Eastern Europe compared to Western Europe, largely because of poor economic conditions. . . . Countries with poor economic conditions have weaker relationships between the social structural variables and prejudice” (p. 20).

CASTE: CULTURE AND SOCIAL STRUCTURE COMMINGLED

As described earlier, “castes” are the defining units of a system of rigid social stratification, sanctioned by custom, law, or religion. Caste systems are characterized by hereditary status, endogamy, and caste-based restrictions on occupation and social contact. As such, caste systems represent a true meld of culture and social structure, so that almost all effects of caste membership can be seen as an interaction between the two. Although the social science conceptualization of caste was originally developed on the basis of the Hindu system, castes exist in many countries and cultures. Examples in West Africa are *forgerons* (ironworkers) and *griots* (oral historians, praisers of famous men). Examples in Europe are tinkers and gypsies. An example in modern-day Japan is the Burakumin—descendants of a caste that worked in occupations associated with death. Burakumin were considered to be below the lowest rung of the traditional Tokugawa Japanese caste system. In that system, the Samurai were officially on the highest rung, followed by farmers, craftspeople, and merchants. It is also the case that the Japanese nobility, based on relationship to the Emperor, could then, and now, be considered a distinct caste, as might also past, and possibly present, European nobles.

A particular complication of caste systems that may affect individuals' attitudes and psychological functioning is that the culturally ascribed social status of the members of particular castes may not be mirrored in their socioeconomic position. An example of this is reported by Biswas and Pandey (1996) in a study of individual mobility and perception of social status among Indian tribal and caste groups. They found an interaction between caste and mobility in the perception of both

status and relative poverty. In the perception of status

mobile scheduled [i.e. very low status] caste . . . groups, even if they perceive their economic conditions as better . . . perceive their social status as lower. . . . The upper class immobile group perceived their social status as higher even though their socioeconomic condition was lower. . . . In the case of the perception of relative poverty, the immobile upper caste people perceived more relative poverty than did the immobile scheduled caste . . . People. (p. 209)

Biswas and Pandey concluded that

in Indian society the upper caste feel entitled to and are expected to have an economically privileged range. . . . That is why the upper caste immobile respondents feel more deprived and relatively poorer than do their immobile counterparts in the scheduled caste . . . groups. The scheduled caste people may have accepted their ascribed low social position and may not feel entitled to greater economic facilities and thus do not perceive themselves as relatively more deprived; they therefore perceive less relative poverty. (p. 210)

Another interaction between caste and social structure occurs when values and modes of thinking that might be predicted as arising from the relative complexity and intellectual demandingness of caste members' educational and occupational experiences are counteracted by values deriving from these caste members' felt needs to preserve the caste's status in society.

An example of this can be seen in a study of the correlates of individualism and collectivism in Sri Lanka (Freeman, 1997). According to Freeman, "In Sri Lanka . . . occupational status is an index of one's rank within a traditional caste hierarchy . . . (homemakers, wage laborer, unskilled . . . professional with advanced degree; senior government or military official)" (p. 327). He predicted that those in high-status occupations would tend to hold idiocentric values stressing individualism and devaluing collectivism. Freeman did so on the basis of reasoning analogous to that underlying the Kohn and Schooler (1983) and the Schooler et al. (1999, 2004) studies on the psychological effects of occupational conditions. "Post hoc analyses revealed that, quite opposite to prediction, a group of highly educated individuals, also high in occupational status, received some of the lowest idiocentrism scores in the entire

sample. These are the high caste, 'traditional elite' of the country" (p. 333). Freeman explained this unexpected finding by noting that

[a] traditional system of caste by definition is opposed to the idiocentric values of independence and self-determination. These values would understandably be rejected by the traditional elite, because they represent a threat to the social system that supports the high status of this group. By the same token, by endorsing idiocentric values, educated lower- and middle-caste respondents may be expressing a rejection of the traditional status quo, and also expressing their aspirations beyond a low or intermediate status in the caste system. (p. 333)

Freeman notes that it is pertinent "that other social change theorists have observed similar patterns in other traditional cultures, such that the middle classes are most receptive to the processes of change in the status quo, whereas, the traditional elites and uneducated lower classes, albeit for different reasons, tend to be more resistant to change" (p. 333).

CONCLUSIONS

I hope that these theoretical discussions and empirical examples of the interconnections of social structure and culture have succeeded both in raising the methodological concern and piquing the theoretical interests of cultural psychologists. In terms of cultural psychologists' methodological approaches, given the above examples of how individuals' positions in the social structures of their societies can notably affect their psychological functioning, it is important that cultural psychologists pay attention to social-structural issues in designing their research. The importance of their doing so is increased by the possibility, illustrated by these examples, that cultural and social-structural factors may interact so that the effects of culture on psychological functioning may be dependent on the social-structural statuses of the individuals being investigated while, conversely, the effects of social-structural position may be affected by culture.

It would seem to sometimes be the case that when the "expected" psychological outcomes of being in a particular social-structural position challenge the traditional values and self-views of those in that position, the length of time that it takes for such effects to occur is ex-

tended, if they occur at all. Among examples of this tendency that I have discussed are (1) the unexpectedly high levels of authoritarianism–conservatism among Japanese managers, (2) the more positive than might be expected self-views of relatively upper status castes that have had recent histories of downward economic mobility, (3) the less positive than might be expected self-views of low-status castes that have histories of recent upward mobility, (4) the relatively socially conservative authoritarian views of high-caste, elite Sri Lankans. What social scientists cannot say, or even hypothesize, at the present time is under what conditions such, or other, interactions between culture and social structure are likely to occur.

Given the demonstrated effects of social status on psychological functioning among individuals in the same society, and the evidence that these effects may be affected by interactions with culture, it is probably best that general conclusions about cultural differences between societies be based on samples that include a wide range of the statuses in the societies being compared. It is probably not sufficient to limit comparisons across cultures to individuals in the same social–structural position or positions, although, in many instances, doing so provides some level of control.

Unfortunately, the proviso about the dangers of basing conclusions about cross-cultural differences on studies of individuals in a single social–structural position applies to college students, who occupy a status that has been the focus of a large proportion of the research, particularly experimental research, in cultural psychology. Reason for concern about the general dependence on college students as experimental subjects in psychology experiments was provided over a decade and half ago in a review by Sears (1987; see also Schooler, 1989). Sears showed that the great majority of social-psychological studies conducted from the early 1960s until the time of his article had relied almost exclusively on college students tested in the laboratory. The most prestigious research was, if anything, more likely to have done so. These trends seem to have continued until the present. Sears also presented evidence suggesting the possibility that such subjects are likely to have less crystallized attitudes, less formulated senses of self, stronger cognitive skills, stronger tendencies to comply with authority, and more unstable peer group relationships than do older adults. He concludes that these

peculiarities of social psychology's predominant database may have unwittingly, and perhaps misleadingly, contributed to such major substantive conclusions: that people are easily influenced, behave inconsistently with their attitudes, do not rest their self-perceptions on introspection, and are highly egocentric. Sears also raised the possibility that this database may have contributed to the strong emphasis in contemporary social psychology upon cognitive processes. In terms of cultural psychology research, it is also quite plausible that the selection processes that affect the level and nature of an individual's education may differ across countries, resulting in psychological differences among individuals of nominally equivalent educational levels. Similarly, as seen in the case of authoritarianism, there is evidence that systematic cross-national differences, such as those in educational processes, may also lead to theoretically important differences in the psychological characteristics of individuals at nominally equivalent educational levels (e.g., college sophomores). Given these trends and possibilities, it is incumbent on cultural psychologists to base their conclusions on individuals from a range of educational levels. More generally, given the possibility of interactions such as those found between culture and social structure, it would seem to be important when describing the psychological effects of a society's culture, that cultural psychologists specify the segments of society to which they believe their conclusions apply.

The importance of taking social structure into account when considering the psychological effects of culture goes beyond a concern for placing appropriate limits on the extent of the empirical claims one makes. Paying attention to social structure is also important for understanding how culture and social structure function, how each affects the other, and how they may interact in having their psychological effects. An example of how social structure and culture may affect each other can be seen in the ramifications of the findings described earlier, that across a number of industrialized cultures, intellectually demanding work on the job increases intellectual functioning and individualistic self-directed orientations to self and others. These findings strongly raise the possibility that changes in a society's modes of production and distribution may affect the cognitive functioning, orientations, and values of its members. As noted earlier, it is just such societal dif-

ferences in modes of production and distribution that the various theories reviewed by Cohen (2001) hypothesize to underlie the cultural dissimilarities and consequent psychological differences that are of central concern to cultural psychologists. One example of such concern with the effects of modes of production is Nisbett and Cohen's (1996) theoretical explanation of how a history derived from herding-based economy led the Southern United States to develop a culture of honor, with its psychological and behavioral consequences. Another example is Nisbett's (2003) tracing of Asian versus Western psychological differences to differences between cultures deriving from societies originally based on the large-scale, cooperative agriculture that was predominant in Asia as opposed to the subsistence, small-scale agriculture that characterized much of ancient Europe.

In terms of social-structural effects, it is important to note that not all social statuses within a given society may be similarly affected by a particular set of societal changes. Nor may all social statuses within a society be in similar positions to affect that society's cultural values. Given these possibilities, changes in a society's culture may come to be affected by not only the number of individuals whose psychological functioning and beliefs are affected by changes in a society's production or distribution of its "goods" but also the social-structural positions of the individuals whose psychological functioning and beliefs are so changed—hence, the theoretical importance of examining not only overall changes in socioenvironmental factors such as the nature of work and its consequent psychological effects in a given society but also the distribution of such changes within that society's social structure.

The possibility also exists of the development over time of a feedback loop between a society's socioeconomic functioning and the intellectual functioning of some of its members. Such a feedback loop might involve several stages: (1) Changes in modes of production and distribution within a particular society lead to increases in levels of occupational self-direction, and hence to increases in intellectual functioning; (2) these increases in intellectual functioning occur among individuals whose positions within that society's social structure lead to the development of new, more effective modes of that society's economic functioning; (3) these new modes of economic functioning

similarly involve increases in the intellectual demands placed on individuals in social-structural positions that permit them to affect their society's productiveness; (4) the resultant increases in level of individual intellectual functioning in such social-structural positions lead to still more effective and plausibly more complex intellectually demanding modes of production. Of course, it is equally plausible that if changes in a particular society's modes of production and distribution lead to a decrease in levels of occupational self-direction among individuals who are in social-structural positions that permit them to affect their society's productiveness, then the result might be a feedback loop that would eventually lead to less effective modes of production, distribution, and intellectual functioning.

The finding that occupational self-direction leads to self-directed orientations to self and society raises the possibility that the degree to which the modes of production within a society promote occupational self-direction may come to affect the level of individualism of that society's cultural norms. Here, too, there may develop over time a feedback loop between the individualistic values of those in particular locations in a given society's social structure and that society's modes of production and socioeconomic operation.

There has been a wide range of sociological theorizing that individualism, through one process or another, encourages economic development. Such a possibility is one of the foundations of Weber's argument in the debate about the importance of the Protestant ethic for the growth of Western capitalism (Tawney, 1963; Weber, 1958). Goldstone's (1987) argument that technical and economic progress is dependent on individuals' being open to innovation, pluralism, and the taking risks also suggests ways in which a self-directed individualistic orientation may encourage technical and economic development. Goldstone attributed the historical economic stagnation of a wide range of countries to the intolerance of innovation resulting from a "suppression of alternatives and emphasis on internal cultural orthodoxy" (p. 132). To the degree that self-directed orientations loosen one's ties to and concerns about the social groups to which one belongs (Macfarlane, 1986; Schooler, 1990b), individuals strongly interested in their own success may also be more willing to engage in risky ventures than would those constrained by concerns over

the repercussions of their actions to the social groups with which they identify. In addition, individuals with self-directed orientations may be freer to act without concern for the constraints that such group ties impose, providing for greater flexibility in both the geographical movement and occupational behavior of workers.

Although there may often be a link between individualistic values and economic development, the existence of individualistic, self-directed cultural norms does not guarantee economic development. Such cultural norms apparently characterize both preliterate, immediate-return hunter-gatherer societies (Woodburn, 1982) and subarctic hunting societies (Ridington, 1988). In neither case did self-directed individualistic orientations lead to economic development. Nor do the orientations and values that individuals within a society derive from their work experiences necessarily have a relatively immediate effect on their society's norms. Many factors, including the effectiveness of the institutions shielding a given society's established norms from change, can affect the degree to which, and the speed with which, the society's cultural norms are affected by the psychological consequences of its members' occupational conditions. Nevertheless, it remains distinctly plausible that such effects can and have occurred. For more elaborated discussions of these issues, see Schooler (1990b, 1994, 1996, 1998).

I began this review by noting the general lack of attention that psychologists pay to social structure as a variable that may potentially affect the psychological functioning of the individual. I hope that in the course of the review I have convinced those interested in cultural psychology of the importance of paying attention to the nature of the social structures of the societies whose cultures' psychological effects they are investigating. Of at least equal importance is that cultural psychologists take into account the social-structural positions of the individuals they are studying within the societies whose cultural effects they are investigating. As we have seen, cultures and social structures can interact both in terms of how they affect each other and how they affect the individual. Consequently, a full understanding of culture, of social structure, and of individual psychological functioning can only be truly achieved if attention is paid to each of these facets of reality and none is neglected.

NOTES

1. Cultural lag—the continuing psychological effects of cultural beliefs and practices in the face of material and social-structural change—has long been noted by sociologists (e.g., Ogburn [1950, 1964]). Evidence for the persistent long-term effects of culture on social structure and psychological functioning is presented by the finding (Schooler, 1976) that, compared to men from ethnic groups whose home countries abolished serfdom relatively early, American men from ethnic groups with a relatively recent and pervasive history of serfdom tend to show the nonindividualistic, conformist orientation, and intellectual inflexibility of men working under environmental conditions characteristic of serfdom. This pattern of findings strongly suggests that the restrictive social and occupational conditions that prevailed within feudal European societies seem to have affected those societies' cultures in a manner analogous to the way the lack of occupational self-direction affects an individual's intellectual functioning and orientations to self and others. The resultant pattern of persistent ethnic cultural differences has continued to affect both individuals' positions in the social structures of their society and their psychological functioning across generations and across the changes represented by industrialization and immigration the United States.

Evidence of the relatively more rapid effect of social structure on psychological functioning than of psychological functioning on social structure can be found in the Kohn and Schooler (1983) findings that the effects of social-structural position, as represented by such components of occupational self-direction as substantive complexity and closeness of supervision, have relatively contemporaneous effects on such aspects of psychological functioning as ideational flexibility and distress, whereas the reciprocal effects of these aspects of psychological functioning on job conditions tend to be lagged.

2. "Intellectual flexibility," the SEM measure of intellectual functioning used in the Kohn and Schooler (1983) studies, is defined as cognitive flexibility in coping with the intellectual demands of a complex situation. Its indices include (1) a summary score for performance on the Embedded Figures Test (Witkin, Dyk, Faterston, Goodenough, & Karp, 1962); (2) the interviewer's appraisal of the participant's intelligence; (3) the frequency of agreement with agree-disagree questions (because some of the questions included in the battery are stated positively and others negatively, an overall tendency to agree suggests that the participant is not thinking carefully about and is less differentiating about the questions); (4) the degree to which the answer to the question "What are all of the arguments you can think of for or against allowing cigarette commercials on TV?" provided reasons for both sides of the argument; and (5) the answer to a question about how to decide between two alternative locations for a hamburger stand (with answer adequacy being judged by a concern with potential costs, potential sales, and the understand-

ing that profits result from the difference between the two). The intellectual flexibility measure was highly correlated ($r = .86, p < .0001$) with a standard cognitive functioning factor based on standard cognitive tests introduced in the 1994 survey (i.e., immediate recall, category fluency, number series, verbal meaning, identical pictures, and different uses; Schooler, Mulatu, & Oates, 1999).

PART IV

**ACQUISITION AND CHANGE
OF CULTURE**

CHAPTER 16

Food and Eating

PAUL ROZIN

As its name indicates, with “cultural” modifying “psychology,” cultural psychology is a branch of psychology. Although extending the scope and depth of psychology, it has appropriately accepted the organization that psychology has imposed on its phenomena. That orientation, unlike the orientation in anthropology or zoology, focuses on basic underlying processes, such as perception, attention, cognition, and emotion. Indeed, the document proposing this volume notes that its middle section will be organized “in terms of domains of cultural-psychological empirical research. There will be sections on identities, cognition, emotion and motivation, interaction and social relationships, and socialization.” The process orientation that has dominated psychology for more than a century, documented by P. Rozin (in press), has proved very productive. But, especially with the reemergence of mind as the central concern of psychology in the late 20th century, the process orientation has focused almost entirely on the features of minds, at the cost of ignoring the domains of life, the institutions, cultural environments and practices that constitute most of daily life (P. Rozin, in press). It is these latter aspects that have dominated the fine ethnographies provided by anthropologists over the century, and that formed the empirical basis for the serious consideration of culture within psychology.

The fields of cognitive science and evolutionary psychology, following on changes in orientation to animal learning, have become more involved with domain-specific adaptations. It seems appropriate to at least raise the possibility of a different organization of cultural psychology. This would organize the field around the major domains of life: eating, sex, protection (including housing and clothing), parenting, etc. Unfortunately, it is virtually impossible to accomplish both a process and life domain segmentation of a field at the same time. However, for this volume, at least two exceptions to the process approach have been incorporated: one is a chapter on religion, and the other, this chapter on the domain of food and eating. Although food is clearly central to both culture and human biology, it has been little studied by psychologists in general, or by cultural psychologists specifically. This state of affairs results primarily from the process orientation in the field, as well as long-term (but diminishing) assumptions about the adequacy of domain general principles to account for behavior. This chapter attempts to organize what we know about food and culture, and to argue for a central role for the study of food and eating in cultural psychology.

Because the study of food (except for obesity, eating disorders, and the regulation of intake) is almost absent from psychology, I provide

here a set of references to orient a reader to what is known about this area, principally from disciplines other than psychology—from the anthropological/evolutionary perspective: Diamond (1996), Harris (1985), Harris and Ross (1987), Katz (1982), and P. Rozin (1982); from a more general cultural perspective: DeGariné (1972), Mead, (1943), and Messer (1984); from the ethnographic perspective (e.g., especially informative food-related ethnographies): Meigs (1984), Ohnuki-Tierney (1993), and Whitehead (2000); from a sociological perspective: Beardsworth and Keil (1995), Murcott (1983), and Maurer and Sobal (1995); and from a more psychological and biological perspective: Booth (1994), Logue (2004), Meiselman and MacFie (1996), P. Rozin (1976; P. Rozin & Schulkin, 1990), and Shepherd and Raats (2006). Important cultural–historical perspectives are provided by Kass (1994), Levenstein (1988, 1993), Simoons (1991), and Whorton (1982). A few authors provide a broad, general perspective, including Barker (1982), Fischler (1990), Katz (2004), Kiple and Ornelas (2000), and Meiselman (2000).

THE FOOD–EATING DOMAIN

Food has to do with one of the basic domains of survival. It is central in animal life: food search, identification, and ingestion probably accounts for most of the waking time of most animals. Food selection is perhaps *the* single most important force in animal evolution; if you want to know as much as you can about an unknown animal, the best thing to ask, other than about its phylogenetic classification, is “What does it eat?” This single fact is highly informative about the sense organs, physiology of the digestive system, motor abilities, and learning or cognitive capacities. Animals that eat a very narrow range of foods are highly tuned to detect and appropriate their prey: Examples are anteaters, the carnivorous mammals, and specialized herbivores, such as pandas and koalas. More generalist animals have a broader but less specialized set of skills and structures, and are generally more well developed in what we loosely call intelligence (see Milton’s [1993] article on the relation between brain size and diet in monkeys). A generalist animal faces a great set of challenges: finding combinations of foods that are nutritive, bal-

anced, and minimally toxic. I can imagine no other task that is more intellectually demanding, though, surely, mastering complex social organizations (e.g., Humphrey, 1976) is also deeply complex and challenging (and sometimes related to feeding patterns or strategies). So a first reason to be interested in food in cultural psychology is that it is such an important part of our primate heritage and so closely linked to intelligence.

A second reason that suggests food as an important area of study follows from the recent increase of interest in affect in psychology. Food is one of the major sources of affect. Eating is at the same time satisfying and threatening. It is a necessary and frequent part of remaining alive, because it provides the only source of energy and life-sustaining nutrients. On the other hand, many of the possible edibles in the world are toxic or are vehicles for dangerous microorganisms. Presumably, for this reason, people (and other animals) feel very strongly about what goes in their mouths; they are rarely neutral on this point. The stakes are high. For humans, another dimension amplifies the affective response to foods. It is widely believed in traditional cultures that a person takes on the properties of the foods he or she eats (“You are what you eat”). In this context, eating can have moral import, and can affect a person’s personality and fortunes. “You are what you eat” is an eminently sensible idea; when we mix two things (in this case, a person and the food she eats), it is natural to believe that the product reflects both of the constituents. Although modern biological science makes clear that there are no grounds for believing that properties such as moral status or personality could be transmitted by the molecules that result from the process of digestion, it has been shown that even educated Westerners believe, implicitly, that one takes on the properties of what one eats. Nemeroff and Rozin (1989) asked two groups of American students to read a few paragraphs about a culture, then answer questions about the people in that culture. Both groups read the same description, except that one culture was described as eating boar and hunting, but not eating, marine turtle, and the other as eating marine turtle and hunting, but not eating, boar. The boar-eaters were later rated as having more hair, and as being more aggressive, faster runners, and showing other boar properties (and fewer turtle properties) than the turtle-eaters.

Other arguments for a cultural psychology of food and eating derive directly from human issues, and human culture. Food selection and procurement figure prominently in almost all theories of the evolution of humans, with a shift from a more plant-dominated forest diet to a diet with more animal protein in the savannah environment. Animals are generally harder foods to procure, so that more demands are made on motor capacities and sensory abilities. But a diet relying on animals does relieve a creature of the risks of dietary imbalance. All animals are made of roughly the same molecules, so almost any animal is a good source of nutrition. Not so for plants, which are often incomplete or imbalanced sources of nutrients for animals, and must be eaten in appropriate combinations. For the human omnivore, seeking animal food but still consuming a wide range of plant foods, there are two challenges: procurement of food (most challenging for animal prey) and appropriate food selection (most challenging to the degree of reliance on plant foods).

If there is a prominent advance that set humans on the course to elaborated culture, it is surely the development of agriculture and domestication (Diamond, 1996). These powerful human advances, made primarily some 4,000 to 10,000 years ago, provided humans with a steady and efficient food supply. This allowed for larger aggregations of humans, and for the specialization of labor inside and outside the food domain that prompted all sorts of technological advances (e.g., guns and steel, as Diamond eloquently argues). So, in the evolution of human culture, food provides a critical opportunity for extended development of other domains of life, including all sorts of crafts, aesthetic practices, and high technologies.

In contemporary human life, work and food are usually the two major categories of waking activities. Activity logs from 14 cultures, painstakingly documented by Szalai (1972), reveal that (for three cultures that I have tabulated—Peru, the United States, and France in the early 1970s) at 13.2% of total time (including food-related activities: eating, shopping, preparation, cleanup), food is third behind sleep (36.7%) and work (16%). And, of course, much of work is devoted to earning money or trade that is ultimately spent on food. Indeed, among the traditional cultures of the world, including China and India, themselves about a third of humanity, food is the principal source

of expenditures, amounting to about 50% of total expenditures (Samuelson, 1990). In more developed cultures, such as Western Europe and North America, food drops down to 20% or considerably less of total expenditures, but these cultures constitute a minority of the world.

So two more reasons for being interested in food, besides its importance in animal life and evolution and its high affective loading, is its importance in both human evolution (biologically and culturally) and its importance in contemporary daily life.

There are further, discipline-related reasons for the study of food to be of particular interest to psychologists in general, and to cultural psychologists in particular. First, food is a major subject of thought, because the need for it is so compelling, and obtaining it is so challenging. It is likely that many of the features of intelligence so important for humans arose first in solving problems in the domain of food. “What is edible and what is not” is one of the most critical problems facing the young human omnivore. Powerful plastic adaptations to discover the effects of ingested food (e.g., conditioned taste aversions) stand out among learning abilities, and use of food as reinforcement is the central technique of the psychology of learning. Siegal (1996) has argued that in child development, the first domain in which nascent intellectual abilities appear often concerns food and the detection of toxicity.

Second, food and eating are unique among our basic biological systems with respect to human culture. The other systems, including breathing, excretion and sex, maintain much of their nonhuman primate character even in elaborated human cultures. It is the remarkable stability of human mating systems under the impact of powerful cultural change that puts mate selection at the center of evolutionary psychology (Buss, 2004). Food, on the other hand, is the one biological system that has been massively transformed by culture into a range of meanings and practices, cuisines, social events, such that the nutritional function of food is often overshadowed by its social functions. There is nothing quite like dinner, let alone a dinner “party,” for our other biological functions. This unique elaboration of food is the subject of Leon Kass’s (1994) remarkable book, *The Hungry Soul*, in which he documents the transformation of food from a source of nutrition to a socially meaningful

substance in biblical through European history. As Kass notes: "An activity that is inherently ugly is beautified by graceful deed and tactful speech. An activity that is violent and destructive is tamed by gentle manner that keeps its destructive character mostly out of sight. An activity that deforms and dissolves living forms is given form-ality of its own by the work of the human intellect" (p. 154). Or "We eat as if we don't have to, we exploit an animal necessity, as a ballerina exploits gravity" (p. 158).

Third, a remarkable thing has happened to the world of food in developed cultures toward the end of the 20th century. Technological advances have virtually inverted our food environment, so that our adaptations to our ancestral environment are now often maladaptive. This is discussed in a later section.

THE BIOLOGICAL FOOD SYSTEM: THE HUMAN GENERALIST AND SOME FOOD UNIVERSALS

The food generalist faces a daunting food choice problem. Obtaining adequate nutrition involves satisfying the body's persistent need for some 40 nutrients, including many specific amino acids, some fatty acids, vitamins, minerals and water. In the course of satisfying these nutritional constraints, the generalist must also attain adequate energy from a mixture of proteins, fats, and carbohydrates. This set of nutritional requirements can be met easily if there is a fair amount of animal food in the diet, but also by choosing a broad diet among plant foods. However, the generalist faces a dilemma, because in the course of sampling the potential food environment widely, he is likely to encounter potential foods with toxic components or harmful microorganisms. The former are more likely in plants, the latter in animal foods. The risks of eating broadly are high, as are the benefits resulting from the ability to survive in diverse environments. There are no simple ways to avoid toxins and infective agents reliably on sensory grounds, nor to avoid potential foods that have minimal nutritional value. For the most part, this must be learned.

The food generalist, particularly the mammalian generalist (as exemplified by the relatively well studied domestic rat, *Rattus norvegicus*, and human beings), faces serious challenges in both the selection of a balanced diet and the avoidance of harmful or useless potential foods. He is equipped with some bio-

logical adaptations to aid in what must ultimately be primarily a process of acquisition. One set of genetically produced adaptations establish at a modest level some of the adaptations characteristic of specialist animals for particular foods or nutrients (P. Rozin, 1976; P. Rozin & Schulkin, 1990). In full form, this type of adaptation includes an internal state detector, which indicates a need for a certain nutrient, and a sensory detection system, which identifies the presence of that substance in the environment. For a koala, a "univore" surviving almost entirely on eucalyptus leaves, one simple system of this sort is all that is necessary for a complete food selection system: an internal detector indicating a need for food (e.g., "hunger"), and a sensory ability to recognize appropriate food (in this case, a "eucalyptus detector"). Acquisition of energy guarantees acquisition of necessary nutrients.

There are some genetically prepared biological aids to food selection in the mammalian generalist, what have been termed "specialists" within the generalist (P. Rozin, 1976). Thus, for water, there is a specific system that signals a need for water ("thirst") and a specific recognition of the sensory characteristics of water. There is also a dedicated taste system for sodium ions, a critical mineral requirement, and there is some evidence for a central detector system to indicate a need for sodium (Richter, 1956; Denton, 1982; Schulkin, 1991). It is possible that there are a few other specific mineral identification and detection systems. There is a well-investigated energy-state detection system, signaled by an internal state usually described as "hunger." Although there are no very reliable sensory indications of the presence or absence of energy in a potential food, the sweet taste is a reasonable indicator of the presence of sugars, and the detection of fatty textures also indicates the presence of calories in the form of fat. Finally, a bitter detection system allows for rejection of classes of entities that include common toxins.

Overall, in the sensory domain, then, there is strong evidence for an innate preference associated with sweet (sugars), and an innate aversion to bitter, associated with toxins. These innate preferences and aversions have been clearly demonstrated in newborn infants (Steiner, 1979; Rosenstein & Oster, 1988). As well, there are indications of innate preferences for salt at some concentrations (Beauchamp, 1981). A definite preference for fatty textures is

probably innate but has not been demonstrated in newborns. The combined sweet and fat preferences result in strong adult preferences for mixtures of the two (Drewnowski & Greenwood, 1983). Two well documented infant taste aversions are not as easy to tie to nutritional adaptations. An innate and present-at-birth aversion to sour (acid) tastes (Steiner, 1979; Rosenstein & Oster, 1988) does not correspond to any obvious threat to health; it could perhaps represent a bias to avoid unripe fruit in favor of more nutritive ripe fruit. Aversions to chemical irritants (such as chili pepper), prominent in young children, are probably present at birth. It is not clear what these are protective of, because most natural irritants are not harmful. In short, a suite of probably innate taste biases *help* the generalist to solve the food selection problem, but they do not solve the problem. None are effective with respect to microbially contaminated food, and there are safe and nutritive natural entities that trigger the innate avoidance systems.

So far as we know, unlike the hedonically marked and innately biased taste system, and some similar adaptations in the common chemical sense and perception of oral texture, there are no strongly marked innate olfactory biases (Bartoshuk, 1990). The most likely candidate would be an innate avoidance of decay odor, because of its association with potentially harmful microbes. There is no evidence that such a system exists; indeed, young children seem attracted to decayed material, including feces (P. Rozin, Hammer, Oster, Horowitz, & Marmara, 1986). Children of about 2 years of age or less will put virtually anything in their mouths, including what is described as and appears to be feces.

Sensory biases do not exhaust the innate behavioral repertoire of the generalist. It is in the nature of the generalist to be both interested in new potential foods and cautious about them, because they may be toxic or infected, or simply poor sources of nutrition. This combination of risks and benefits manifests (in rats and humans, where it has been studied most) in an interplay between fear of the new (neophobia) and attraction to the new (neophilia). Nowhere is this more apparent than in the behaviors of wild rats (Barnett, 1956). What is familiar is safe, but it restricts the nutritional horizon in ways that may be maladaptive as the environment changes. A common "solution" to what I have called the

"generalist's dilemma" is the cautious sampling of potential new foods.

Finally, an impressive set of adaptations aid the generalist in discovering the nutritional consequences of things ingested. Unlike most forms of learning, in which the consequences of an action or experience are rapid, there is an inherent delay between the action/experience (eating) and its metabolic consequences in the food system. Digestion takes time. It is now well established that a robust learning system connects tastes with their delayed consequences. In its most prominent form, conditioned taste aversions, this system allows for the association between a taste and a negative consequence (e.g., nausea) that may occur even hours later (Garcia, Hankins, & Rusiniak, 1974; P. Rozin & Kalat, 1971). There is a corresponding, usually weaker ability to associate tastes with delayed positive (nutritional) consequences (Garcia, Ervin, Yorke, & Koelling, 1967; Sclafani, 1999).

The digestive system and other parts of the body (e.g., the fat stores) work along with behavioral adaptations to solve the problem of acquiring adequate nutrients and energy. Thus, the liver constitutes a short-term store of energy (in the form of glycogen), and fat deposits in the body form a long-term store. Together, they allow the animal to endure periods of food shortage, usually measured in hours (e.g., between meals), days, or weeks. Metabolic pathways, often predominantly in the liver, allow for detoxification of low levels of dietary toxins, the conversion of energy forms, such as the synthesis of fat from carbohydrate, and the synthesis of important molecules, such as proteins and some amino acids.

One cannot help but be impressed by the enormous variety of foods and eating patterns across humanity. Indeed, ethnic cuisines would have no appeal if we all ate the same things in the same ways. But the metabolic requirements and behavioral biases I have discussed do result in a substantial number of food/culinary universals or near universals in humans. One should also be open to considering *near* universals, because human ingenuity has allowed the invasion of very inhospitable environments, such as the Arctic, that severely constrain nutritional options.

The frequent need for energy, water, and nutrients guarantees that all humans eat (and drink) rather frequently, normally more than once a day. Given that humans are not adapted

to consume very low calorie density foods, such as leaves, they almost always eat rather energy-rich foods in concentrated periods of time, called meals (Pliner & Rozin, 2000). Although meals are not necessary (as opposed to continuous grazing) nutritionally, our digestive system is adapted to consuming and processing much more food than is immediately needed, and time can be spent more efficiently (from the point of view of attending to other needs, conserving energy, and avoiding predation) if eating activities are clustered in time. The availability of animal foods, and elaborate preparations of foods, encourage organization of eating in terms of meals.

Virtually all human beings consume some combination of plant and animal foods. In most cases, males are more involved in the procurement of animal foods, and females in the procurement of plant foods, with females more involved in the preparation of foods for ingestion. Eating at meals is usually a social occasion. Sharing of food is a form of bonding—throughout the world, one shares food with those with whom one is close, and this sharing (“shared substance”) reinforces the closeness. Thus, food is interpersonally important. Although to some degree foods are consumed raw in all cultures, there is some processing of many foods before ingestion. This includes physical changes (removing shells, grinding), mixing of foods, and cooking. Almost all groups of humans can be described as having a cuisine: a set of rules about eating, and a set of “recipes” for the preparation of foods. These are discussed later, but include, among other things, the addition of group-specific characteristic flavors (“flavor principles”) to staples (E. Rozin, 1982). Similarly, almost all human groups exploit some staple grain as a cheap source of energy. Finally, food is universally used as a reward for children and adults, and cuisines and food habits constitute part of a group’s identity.

THE TRANSFORMED BIOLOGICAL MOTIVE: PREADAPTATION AND THE FUNCTIONS AND MEANINGS OF FOOD IN CULTURAL CONTEXT

Leon Kass (1994) captures the major transformation in eating by humans with the contrast between the German verbs *fressen*, eating by animals, and *essen*, for eating by humans. Unlike almost all other animals, humans bring

food to their mouth rather than bringing their mouth to the food. Humans eat using implements, have table “manners,” engage in complex social/informational exchanges during eating (at meals), elaborate foods extensively before eating them, and eat foods in specific orders. In short, eating is an expression of human civilization. Food has become much more than nutrition. As noted in the introduction, food is unique among the biological domains in the degree to which it has been transformed culturally. Food is used by humans for much more than nutrition.

Preadaptation, the process that accounts for the expansion of the food domain in the history of human cultures, was appreciated by Darwin and has been expressed in fuller form by some more modern evolutionists, particularly Bock (1959) and Mayr (1960). It involves the use of an already existent (usually evolved) structure for a new purpose. According to Mayr, preadaptation is the main source of evolutionary novelties and the principal process in speciation. It essentially involves a recombination of existing structures and genes rather than creation of new genes by mutation. One of the finest examples of preadaptation has to do with the food system. The mouth, with its elaborations of teeth and tongue, is an aperture designed to take in nutrients (and air). Clearly, the tongue and teeth have evolved to facilitate the processing of food. But in human evolution, the teeth and tongue, and the entire oral cavity and its link to the respiratory system, are utilized by the language system for the expression of speech. It is noteworthy that the teeth and tongue did not evolve to facilitate language, but were rather opportunistically used by the speech system. To take another example relevant to food, a good argument can be made that the species of plants and animals that were domesticated thousands of years ago were selected by humans because they were preadapted, in terms of social organization, mode of reproduction, and so on, to be useful to, and manageable by, humans.

Preadaptation is even more fundamental in cultural evolution than it is in biological evolution (P. Rozin, 1999a). This is because variation in cultural evolution can be directed by purpose, whereas in biological evolution, the occurrence of variations is dependent on random processes. If a cultural tradition, practice, artifact, or institution might be adaptive in a new context, it can just be transplanted. One

does not have to wait for the opportunity to arise by generation of random variants (a very unlikely event, if the use in a new context requires a series of adaptations). Thus, one can combine the virtues of the calculator and typewriter to create a computer, or apply a culinary technique discovered in one culture to another. The flowering of food from nutrition to a complex expression of civilization (Kass, 1994) has taken place along a number of lines, presumably to different degrees and in different temporal orders of evolution in different cultures (Figure 16.1). Early in human evolution, food became an entity of social significance. The meal became a center for social interaction. Food became central to important cultural events. Food sharing became explicit and implicit forms of expression of interpersonal intimacy. Food became a marker of the status of the individual (as in the Hindu caste system, or the public consumption of expensive foods), and a form of group identity. Note the description of British sailors as “limeys,” Germans as “krauts,” and French as “frogs.” Food enters the aesthetic domain as cuisine, taking its place next to other human activities with lesser links to our fundamental biology, such as literature, music, and art. Cuisines elaborate the flavors and presentation of food in ways that can hardly be described, in most cases, as motivated by improved nutritional properties. Rather, it is appeal to the palate and the eye.

Food becomes an integral part of the moral/religious domain, such as when it is used in religious ritual (e.g., taking the host in the Catholic church, the Jewish laws of Kashrut). In Hindu India, with more than 800 million people, food can be considered a form of “moral currency”; Appadurai (1981) describes it as a “biomoral” substance. The caste system, which ranks people according to moral purity, is largely defined and defended in terms of food

transactions designed to prevent the food of those less morally pure to become consumed by those higher in the system (Marriott, 1968). In the West, for example, the United States, the moral role of food is muted, though overeating, fast foods, fatty foods, and most clearly cigarettes, take on moral overtones (Stein & Nemeroff, 1995; P. Rozin, 1999b).

Finally, in addition to expanded roles for food as art form, moral, and social vehicle, the vocabulary associated with food is co-opted as a means of describing things that have nothing to do with food; that is, food has a metaphoric function. In fact, food is one of the major sources of metaphor (Lakoff & Johnson, 1980), such as when we say that “Janet is sweet,” or “Let’s get to the meat of the paper.” Metaphor is, of course, a quintessential example of preadaptation: export of a word from its original context to other contexts.

DISGUST AS AN EXAMPLE OF PREADAPTATION AND THE CULTURAL EVOLUTION OF THE FOOD SYSTEM

The role of food as a foundation system to be elaborated in various cultural contexts through the principle of preadaptation is well illustrated in the cultural history of the emotion of disgust (see P. Rozin, Haidt, McCauley, & Imada, 1997; P. Rozin, Haidt, & McCauley, 2000, for reviews). Disgust is and has always been regarded as one of five to 10 basic emotions by psychologists. It is featured by Darwin (1872/1965) in *The Expression of Emotions in Man and Animals*, and figures centrally in Izard’s (1977), Tomkins’s (1963), and Ekman’s (1992) general perspectives on emotion. Following on Ekman’s conception of basic emotions, disgust is characterized as having a particular hard-wired pattern of expression, psychophysio-

FIGURE 16.1. Food preadaptation.

logical response, and behavior. The expression focuses around the nose and mouth, and includes raising of the upper lip, wrinkling of the nose, and often a gaping that involves a drop of the lower jaw and tongue extension (Ekman & Friesen, 1975; P. Rozin, Lowery, & Ebert, 1994). These gestures contribute to the functional outcome of ejecting materials from the mouth and closing the nasal passages. They are quite common among the mammals in general. The psychophysiological event that accompanies the elicitation and experience of disgust is nausea. The behavior is withdrawal from the source of disgust.

In nonhuman animals, disgust is elicited by foods or potential foods that have been experienced to have an “unpleasant” taste; bitter tastes seem innately to elicit the disgust facial expression. The function of the expression seems to both expel or turn away from an offending food and to communicate this food quality to conspecifics. Baeyens, Kaes, Eelen, and Silverans (1996) have demonstrated that humans can acquire a dislike for a beverage (taste) when they consume it at the same time as another, visible person who is making a “disgust” face.

It is clear that in its origin, disgust is a food-related emotion: (1) That is how it functions, virtually exclusively, in nonhuman animals and human infants; (2) in terms of its Latin origins, the word in English (and some other languages) actually means “bad taste”; (3) the nausea that typically accompanies disgust and helps to define it is a response that specifically functions to discourage ingestion; and (4) the facial expression clearly functions to expel food and odors.

In light of these observations, it is quite remarkable that the elicitors of disgust in humans include a wide range of events, only a minority

of which can be traced to food. Elicitors include contact with death or filth, many body products, disliked individuals, and the experience of certain activities deemed to be immoral (e.g., sexual perversions or child abuse). We (P. Rozin & Fallon, 1987; P. Rozin et al., 1997; P. Rozin, Haidt, & McCauley, 2000) have proposed an account based on preadaptation whereby, through culture history (or cultural evolution) and perhaps in normal socialization, a series of stages of expansion of the meaning and elicitors of disgust occurs. Whereas the meanings and elicitors of disgust expand, the basic program (expression, behavior, physiological response) remains roughly the same.

In our posited first stage (see Figure 16.2), elicitors of disgust remain potential foods, but the feature of the food that promotes disgust is not its sensory properties, but the nature or origin of the food (P. Rozin & Fallon, 1987). Thus, a quintessentially disgusting food, such as a cockroach or worm, has usually never been tasted. It is the idea of what it is; it is offensive. Perhaps, the idea is that that incorporation of offensive objects might make the self offensive, by the “You are what you eat” principle.

A particularly interesting feature of this ideational disgust, which we call “core disgust,” is that ideationally disgusting entities are “contagious”; that is, they follow the sympathetic magical law of contagion: “Once in contact, always in contact” (Frazer, 1890/1922; Tylor, 1871/1974; Mauss, 1902/1972; P. Rozin, Millman, & Nemeroff, 1986; P. Rozin & Nemeroff, 1990). If a disgusting potential food (e.g., a worm or cockroach) touches an otherwise edible entity, it renders it inedible and in fact disgusting. This property, although characteristic of ideational disgust, does not hold for the original distasteful (e.g., bitter) dis-

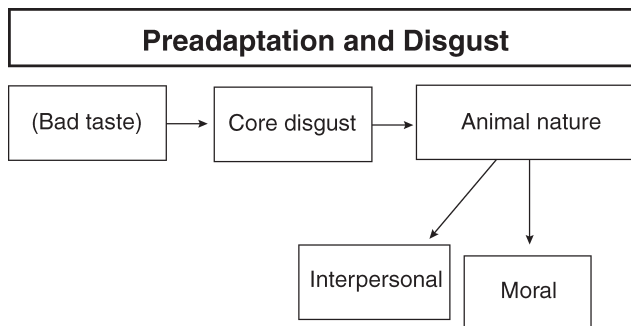

FIGURE 16.2. Preadaptation: Cultural evolution of disgust.

gust elicitors. Because contagion is characteristic of all ideational disgust elicitors and is not characteristic of the more primitive bad taste “disgusts,” we use the terminology *distastes* for bad tastes, and reserve disgust for the culturally acquired rejections that show the contagion property. The contagion property appears to be universal among adult humans but absent in animals or in children younger than about 4 years of age. It seems to be a universal cultural acquisition, perhaps supported by its adaptive advantage in discouraging consumption of infected foods. It is notable, as Angyal (1941) pointed out, that almost all core disgust foods are of animal origin. It is these same foods that have the highest risk as vehicles for transmitting infectious agents.

Feces appears to be the universal core disgust substance. It does not qualify as an innate distaste, since it is not rejected by infants (or most animals; P. Rozin, Hammer, et al., 1986); rather, it is a universally acquired human disgust, with its own fundamental developmental concomitant, toilet training.

We believe that disgust is co-opted as a cultural tool to establish culturally supported aversions or prohibitions by endowing the relevant objects with disgust properties. If a forbidden entity becomes disgusting, it will be naturally avoided, and no rules or formal punishments need be invoked. Such is clearly the case with the outcome of toilet training. A previously attractive substance becomes powerfully disgusting.

By our account, the range of disgust expands from its initial food base to include three other categories of events or elicitors. First, following on the focus on animal foods, it is extended to a wide range of animal features—features that humans share with animals. It is a frequent theme in cultural narratives, rituals, and beliefs that humans are not animals and are superior to animals. Any reminder of the animal nature of humans then becomes undesirable. One animal feature is particularly aversive to humans: their mortality (Becker, 1973; Pyszczynski, Greenberg, & Solomon, 1997). Disgust seems to be used as a device to distract humans from reminders of their mortality. By helping to distance humans from their own animal nature, and from animals, it seems to assist in a major goal that develops cross-culturally as humans evolve. That mortality is at the base of what we will call “animal nature disgust” is supported by two observations: (1) the quintessential odor of disgust is the odor of decay of animal

matter, and that is the odor of death; and (2) psychometrically, disgust reactions to death and things associated with death are among the very best predictors of general disgust sensitivity (Haidt, McCauley, & Rozin, 1994). The rejection of animal nature “stage” of disgust fits with the nature of the civilizing process, as described by the distinguished culture historian, Norbert Elias (1939/1978): “People in the course of the civilizing process, seek to suppress in themselves every characteristic that they feel to be animal” (p. 120).

We have identified two other “domains” or “stages” of disgust; we are not at all sure whether there is a regular order in their developmental or cultural acquisition. One is interpersonal disgust (Figure 16.2), a disgust response to contact with most other individual humans, hence clearly not related to animal nature rejection. Contact, the more intimate the more disgusting, with strangers, disliked persons, or persons from outside one’s own group seem to elicit this type of disgust, which accounts for why “used food” is highly unpopular, as is used clothing, by many people in many cultures. Presumably, this type of disgust has the adaptive value of strengthening ingroup connections and weakening those with outgroups.

Finally, disgust is used to one degree or another depending on the culture to support moral principles; hence, moral disgust. Disgust can be engaged to reinforce a morally cultural based prohibition. The degree to which this occurs seems to be related to the type of moral system a culture has.

Shweder, Much, Mahapatra, and Park (1997) have proposed that three types of moral systems exist across cultures (see Table 16.1). The autonomy system holds that an activity is immoral if it interferes with the rights of an-

TABLE 16.1. Correspondence between Moral Systems and Moral Emotions: The CAD Triad Hypothesis

Rhetoric	Focal concepts	Emotion
Community	Duty, hierarchy, interdependence	Contempt
Autonomy	Harm, rights, justice	Anger
Divinity	Sacred order, natural order, purity	Disgust

Note. Based on Shweder et al. (1997) and P. Rozin, Lowery, et al. (1999).

other person. It describes Western moral systems quite well. The community system identifies immorality as violation of hierarchical structures, such as addressing a respected elder informally. The divinity system considers as immoral any action that reduces one's own or another's purity (divinity). The community and divinity systems are robust parts of morality in many traditional cultures, as demonstrated by Shweder et al. for Hindu Indians. The emotions that involve moral condemnation of others are typically anger, contempt, and disgust. We (P. Rozin, Lowery, et al., 1999) have pointed out that there is a satisfying mapping of these three emotions onto Shweder et al.'s (1997) three systems, with anger associated with autonomy, contempt with community, and disgust with divinity (Table 16.1). We have demonstrated a correspondence between moral offenses of each type and both the emotion words and emotion expressions for each of the three emotions, in both the United States and Japan. Clearly, in a culture in which divinity is an important source of moral principles, disgust will be an important moral emotion. This is illustrated in studies by Haidt, Koller, and Dias (1993), in which they inquired of upper middle-class and lower class Americans and Brazilians whether it was immoral to eat roadkill dog. All respondents felt disgust, but only the middle-class Americans allowed that this was not an immoral act, because nobody was hurt (autonomy was not violated). Because they did not accept a divinity moral system, disgust was not considered a sufficient condition to designate something as immoral.

I have just given a sense of the incredible elaboration of the simple "Get this out of my mouth" emotion into a "Get this away from my soul" emotion. A transition from a "body" to a "soul" emotion—a rich description of this broad function of disgust is described and documented by William I. Miller (1997) in his excellent book, *The Anatomy of Disgust*. This same type of expansion of meanings for food (as opposed to disgust) in European history is described in Leon Kass's *The Hungry Soul* (1994).

Kass (1994) provides a particularly graphic illustration of food, disgust, and civilization. In a typical meal situation in many cultures, individuals face each other while eating. They place food into their mouths, the interior of which is generally regarded as disgusting by others. Furthermore, the mass of chewed food in the

mouth is itself disgusting (both interpersonally and because of its involvement with body secretions, etc.). Remarkably, due to the virtuosity of eating as informed by table manners, this exchange goes on face-to-face without either partner being exposed to any disgust stimuli. More remarkably, the individuals are often conversing while eating, using the same hole to speak that they use to ingest food; still, neither the inside of the mouth nor the ingested food is seen by the partner!

One final interesting feature of disgust in its culturally elaborated form is that it is often funny. Many jokes and cartoons engage disgust, and disgust is typically at the core of humor for young male children. How is it that a negative emotion becomes a source of amusement? Our proposal is that it is one of many manifestations that humans enjoy "constrained" negative events (what we have called "benign masochism"), that is, events that signal threat but are not really threatening (P. Rozin, 1990a). When a well-dressed person other than oneself or partners steps in "dog-doo," it is sort of amusing; not so for the self.

By the same process of preadaptation that expands disgust elicitors in culture history, the process of contagion is carried along with the new elicitors. Thus, contact with an immoral person shows contagion properties; people do not wish to wear Hitler's sweater (P. Rozin, Millman, et al., 1986; P. Rozin & Nemeroff, 1990; Nemeroff & Rozin, 2000).

A comparison of the status of disgust in the United States and India is instructive. Disgust is centered in the core and animal nature domain in the United States, with some extension into the interpersonal domain, and minimal moral disgust. In Hindu India, on the other hand, a good part of disgust engages the interpersonal and moral domain, as illustrated by the caste system, and there is relative insensitivity to animal nature disgust; at least, there is less of a response to contact with death.

CULTURE AND BIOLOGY: SOME FOOD CASE HISTORIES

In this section, I briefly consider the history of some human foods to illustrate how biological, cultural, and psychological factors interact in the cultural evolution of foods (see P. Rozin, 1982, for a more systematic discussion of this issue).

Sugar

The cultural history of sugar is a paradigmatic illustration of how a simple biological predisposition, the preference for a sweet taste, is amplified and elaborated by culture. The innate sweet preference encourages the search for this stimulus and learning about where and when it can be found. In conjunction with the development of agriculture, the desire motivates in humans the cultivation of crops, primarily ripe fruits, that provide this desirable taste experience. Much later in human history, the technology to extract the source of sweetness, sugars, from their natural plant sources allows for the experience of an even more desirable sweet experience. As well, this important advance opens a wide door for expansion of the domain of acceptable foods, because sugar can be added to foods that are otherwise much less palatable, such as coffee or chocolate, and to enhance the taste of traditional dishes.

The search for a source of easily extractable sugar (sugar cane) was a main motivation for the colonization of the tropical Americas by Europeans, and the availability of cheap sugar introduced it to the middle and lower classes, and transformed cuisine in many ways. The extensive culinary and social implications of the availability of inexpensive sugar are well documented by Sidney Mintz (1985) in his book, *Sweetness and Power*. Further technological advances allowed for extraction of sugars from sources other than sugar cane, including sugar beets and corn.

Finally, in the food-flooded modern, developed world, where the calories signaled by the sweet taste are often avoided as opposed to sought, there is the development of artificial sweeteners, uncoupling the taste from the calories that usually go with it, allowing for the experience of the pleasure of sweetness without the calories. All of these extensive advances, with major implications for cuisine and society, are motivated quite directly by the biological predisposition for sweet tastes.

Chocolate

One of the great culinary creations of culture, chocolate, represents a more elaborate version of the amplification illustrated by sugar. It illustrates the creation of a “superfood,” motivated by twin biological predispositions for sweet tastes and fatty texture, both indicators of calo-

ric value. The great appeal of chocolate, one of the favorite foods in the Western world, has to do with its sweetness, fatty texture, aroma, and melt-in-the-mouth quality. Importantly, none of these features are obvious in the wild chocolate bean. So, unlike the case for sugar, the cultural evolution of chocolate involved discovery and development of a potential in a natural product. This extremely complex technology involves both modifying the natural product to enhance some of its properties and adding other things (particularly sugar, sometimes milk and vanilla) to improve palatability and produce variety. The natural chocolate bean is extremely bitter and has neither the aroma nor the fatty texture of commercial chocolate. It was ground and consumed as a beverage in close to its natural form by the Indians of Mesoamerica, well before the arrival of Cortez (see Coe & Coe, 1996, for the history of chocolate). This was an innately unpalatable beverage, an acquired taste.

Brought to Europe by the early Spanish explorers, chocolate was transformed into a luscious food by Western Europeans, and later Americans, in a complex process that involves many stages and, critically, depends on the availability of cheap sugar. The result is a food, source of calories and nutrients that is among the most popular in the Western world, and is presently the most craved substance in North America (Weingarten & Elston, 1991; P. Rozin, Levine, & Stoess, 1991).

The story of chocolate, like that of sugar but more so, is the story of the amplification and elaboration of biological predispositions. The difference is that the aspects of chocolate that satisfy these predispositions are not apparent in the natural product. It is of particular cultural and psychological interest that although chocolate is raised in tropical areas, particularly Africa, South America, and parts of Asia, the great desire for it and consumption of it is in the very countries that cannot grow it: Europe, the United States, and Canada. This may be explained, in part, on economic grounds: Chocolate is expensive, and the tropical countries in which it grows are not wealthy.

Chili Pepper

Chili pepper is probably the most widely consumed spice in the world, other than garlic (if one chooses to consider garlic a spice). It is eaten on a daily basis, usually as part of a sea-

soning sauce used with almost all savory foods by more than 2 billion people every day. It is an essential part of the basic flavoring (“flavor principle”; see the section on cuisine) of most tropical and semitropical cuisines in the world. The contrast with chocolate and sugar is striking, because unlike these two popular foods, chili pepper is innately aversive on account of its oral irritant properties. So chili pepper illustrates the reversal of an innate aversion, a case where culture overwhelms and reverses a biological predisposition (see P. Rozin, 1990a, for a detailed consideration of psychological and cultural aspects of chili use).

All chili peppers come from the Americas and were introduced to Europe by the early explorers of the Americas. They spread later to Africa and Asia. The innately aversive irritation of the peppers, caused by a family of chemicals called capsaicins, were bred out of the imported peppers. This probably happened first in Hungary, and the result was what we now call sweet peppers, which became a mainstay of Mediterranean cuisines. But, in spite of the availability of such mild peppers, it was the “hot” peppers that spread to tropical and semitropical Africa and Asia. It is a remarkable feature of history, and particularly culinary history, that such a “bad tasting” product achieved so much success, particularly when other foods from the Americas, including tomatoes and potatoes, experienced substantial resistance before adoption in Europe and other countries.

The story of the chili pepper and the widespread adoption of other innately unpalatable substances, such as black pepper, ginger, tobacco, and coffee, raise two very important questions for cultural psychology. First, what are the cultural or biological adaptive values of this widespread practice, and second, how does culture manage to accomplish the hedonic reversal? As to adaptive value, there are possible accounts but no certain solutions (reviewed in Rozin, 1990a). Billing and Sherman (1998) have made a good case for the antimicrobial value of spices in general, including chili pepper. Other accounts, each with minimal evidence, suggest nutritional values, thermoregulatory (cooling) effects, and coverage of the taste of spoilage.

From the perspective of cultural psychology, the particular interest of chili pepper and other innately aversive substances and activities is how they are socialized. And most critically, it

is extremely clear that people consume chili pepper because they like its taste; that is, cultural processes lead to a hedonic reversal in which an innately aversive sensation becomes a pleasant sensation! People do not consume chili pepper like a medicine, because they think it is good for them. They consume it because they like it.

We do not have an adequate account of how this happens (reviewed in Rozin, 1990a), but given the generality of cultural adoption of initially aversive substances and activities, I briefly discuss the causes of hedonic reversal for the chili pepper as a model system. A whole family of accounts link chili pepper ingestion to positive effects it produces, including sweating and lowered body temperature, and induced parasympathetic activity (including salivation, gastric secretion, and lowered heart rate) and endogenous opiate release in the brain. All of these effects do occur; the question is their role in the acquisition of liking. To learn from these effects (and somehow, via this learning, transform the hedonic response), repeated exposure is necessary. Normally, when an aversive event or substance is encountered, it is subsequently avoided. So one important effect of culture is to produce an environment, social and physical, in which there is repeated consumption of food with chili pepper in it. Is this a sufficient condition (e.g., Zajonc’s [1968] well-documented “process” of “mere exposure”)?

The answer is clearly “no”; fieldwork and preference tests in the field (P. Rozin & Schiller, 1980) indicate that whereas all Mexicans in a village over the age of 6 or so years like the burn of chili pepper, not a single animal in the same village does so. This in spite of the fact that the dogs, pigs, and chickens consume the daily garbage, which regularly includes stale staple foods and dishes, and excess salsa (the chili pepper-based sauce that is placed on most savory foods; P. Rozin & Kennel, 1983). The reversal of the innate aversion for chili pepper, and almost certainly other entities, seems to be an almost uniquely human accomplishment, and to involve culture as an essential ingredient.

Field measurements (Rozin & Schiller, 1980) indicate that very young Mexican children do not like chili pepper, and that a liking for the hot taste occurs somewhere around 4–6 years of age. There are two reasonable, not conflicting, accounts. One is social: In the meal setting, the entire family consumes food with chili pep-

per in it, or with an accompanying sauce to be added to the foods. There is no overt pressure at the table to consume hot pepper. But the young child observes that older siblings and all adults consume it with gusto, and this experience may in some way produce the hedonic reversal.

A second account, which we call “benign masochism” (P. Rozin & Schiller, 1980; P. Rozin, 1990a), puts chili-liking together with a whole set of uniquely human activities, in which pleasure is produced by the elicitation of negative experiences and/or emotions: riding roller coasters, recreational parachute jumping, going to sad movies, smoking cigarettes, drinking black coffee. The idea is that humans, and only humans, seem to get pleasure out of the fact their body is signaling danger/rejection to them, but they know they are really safe. This body–mind disparity seems to induce pleasure. The case is particularly clear for roller-coaster riding. We have some evidence that this might be the case for the chili pepper, because we have shown that any individual’s most preferred level of “burn” for the chili pepper is the level just slightly below the level of aversive pain (just as the best roller coaster is the scariest, within constraints; Rozin & Schiller, 1980). It is worth noting that disgust humor, discussed earlier, is another possible example of benign masochism.

The important lesson from chili pepper as an example of a learned reversal of innate aversions is that, at a minimum, it invokes cultural mechanisms at three levels: (1) the availability of the substance or experience, (2) the continued exposure to it in spite of its initial negative effects, and (3) in some yet to be fully understood way, the accomplishment of the hedonic reversal.

Ironically, yet another account for hedonic reversal involves endogenous opiate secretion that invokes an opponent process model. According to this view (P. Rozin, 1990a), the adaptive opponent system, which is generally employed to adapt to certain types of events that disturb equilibrium, is over-activated and produces a reversal. Such an account has been used to account for addiction (Solomon, 1980).

Milk

Milk is necessarily the first food of mammals. Until the development of animal domestication and then dairying by humans, milk was a

unique food available only to baby mammals. In the contemporary human world, milk and derivative dairy products form an important part of the diet in many cultures. It is notably absent from most East Asian cuisines but present in some form in most others as a food for children and adults. Milk illustrates a very important point about the relation of biology to culture. The culture history of dairy products shows both how biological constraints affect cultural evolution and institutions, and, importantly, how culture affects our biology. This dual-direction effect is the focus of this short section on milk.

Because milk is unavailable as a food past nursing in the predomestication environment, it would be problematic to have adult mammals seeking their first food. A number of mechanisms have evolved to accomplish not only the weaning from milk but also some decline in its preference (reviewed in P. Rozin and Pelchat, 1988). The most relevant mechanism is genetically programmed lactose intolerance (see Simoons, 1969, 1970). The only carbohydrate in mammalian milk (with a few minor exceptions) is lactose, a sugar that is the combination of two simpler sugars, glucose and galactose. Lactose is found only in milk. Lactose, which cannot be absorbed directly, is broken into its two utilizable subcomponents by the gut enzyme, lactase. This enzyme, present in the gut of virtually all mammals, is deprogrammed such that it gradually disappears at about the time of weaning of the species in question. Undigested lactose ferments in the hind gut, producing gas pains and diarrhea, and interfering with absorption of some of the nutrients in milk. These unpleasant symptoms very likely contribute to the weaning process. Preagricultural humans were therefore like all other mammals and unable to utilize milk effectively after weaning.

Domestication made milk available as an adult food. There is convincing evidence, largely from the work of Frederick Simoons (1969, 1970), that two very different types of adaptations occurred since the origin of domestication to encourage the availability of milk and its products in the postweaning human diet. First, cultural innovations adapted to a biological limitation (adult lactose intolerance) by digesting milk outside of the body, breaking down the lactose into its utilizable components before ingestion. This was done with microorganisms and results in products such as cheese

and yogurt. These appropriately termed “cultured” products make the carbohydrate in milk utilizable and bypass the negative symptoms.

A second set of biological adaptations occurred subsequent to the rise of dairying. In a group of cultures primarily from Northern Europe, but also including some pastoral groups in Africa, the availability of dairy food set up a situation in which the ability to digest milk was adaptive. There is a single gene mutation that, when it occurs, blocks the deprogramming of lactase production at weaning. In these cultures, the occurrence of this mutation improved survivability, and gradually the gene frequency rose. The result is that most people of Northern European origin (and a few African groups) retain their lactase and can drink raw milk throughout their lives. They are lactose tolerant adults. Hence, a cultural advance changed the adaptive landscape for humans and induced a genetic change in some groups of humans.

The main point is the dual direction of culture–biology change so well illustrated by milk. Many issues related to dairy products may engage cultural psychology, but these are not be dealt with here. Of particular interest is why Chinese cuisine, one of the world’s major cuisines, includes no dairy products. This may have a cultural–historical explanation: The Chinese were ruled by despised Mongols for a long period and the Mongols are heavy dairy consumers.

Meat

Meat should be a subject of special interest to psychologists, because it is a quintessential example of the interesting and important state of ambivalence. It is at the same time the most tabooed and the most favored food across the human race. Meat is a charged entity, imbued with multiple meanings. Because it is the food whose composition is most similar to that of humans, it is the most complete of foods. But this same similarity makes meat most likely to be the host to microorganisms that also find a happy home in humans. Meat is most nutritive and most infective. Obtaining meat involves hunting and killing animals, an act that requires great skill and is at the same time morally questionable. The anthropologist Stanley Tambiah (1969) elaborated some of these points in a well-known paper entitled “Animals Are Good to Think and Good to Pro-

hibit.” He might as well have replaced the word *think* with *eat*.

Meat, represented in terms of the most favored parts of animals, is in traditional societies often restricted for the consumption of males, or the more important males. At the same time, in some cultures, some religions, and among some individuals within meat-eating cultures, prohibition of all meat is practiced. Vegetarianism has a long history and a wide geographical presence. Meat is the only general category of foods that is widely prohibited. Almost all objects of food disgust cross-culturally are animals or animal products (Angyal, 1941; P. Rozin & Fallon, 1987). This can, perhaps, be related to the role of disgust in denying our animal nature, as well as in the “You are what you eat” principle (eat an animal and become animal-like; Nemeroff & Rozin, 1989). Of course, cannibalism, often the most negatively regarded human food practice, is a special example of meat eating.

The place of meat in human life has been treated by a number of authors, including Marvin Harris (1985), from an evolutionary perspective; Frederick Simoons (1961/1994) from the cultural–geographic perspective, with a focus on meat taboos; Julia Twigg (1983) from the vegetarian perspective, and other authors in more general treatments (e.g., Beardsworth & Keil, 1997; Fiddes, 1991; P. Rozin, 2004).

CUISINE

Eating involves incorporating substance; humans typically do something to the things they find in the world before consuming them. Some of this amounts to physical preparation such as peeling or cutting, but much involves more elaborate transformations, including mixing, grinding, cooking, and flavoring. These behaviors conveniently often leave substantial records that can be examined by archeologists (unlike sex, for example); it is not as good as writing, but it is a meaningful record. Of course, when combined with writing, the food domain results in recipes and cookbooks.

We can use the word *cuisine* to represent the body of shared rules, beliefs, and practices relating to food within any culture. Regularities are sufficiently great within cultures that we can usually identify the culture by examining what is eaten.

At the level of the “dish,” Elisabeth Rozin (1982) points out that there are three components: staple foods, processing techniques, and flavorings. She notes that most cuisines add a particular set of flavoring ingredients to most savory dishes, and calls these “flavor principles.” Thus, Southern Italian cuisine is characterized by tomato, sweet pepper, olive oil, and oregano as flavorings. Chinese cuisine typically flavors with soy sauce, ginger root, and rice wine, and Mexican cuisine characteristically uses chili pepper with either lime or tomato. Flavor principles provide a distinctiveness/identity to the foods of a particular group, and offer a sense of comfort and familiarity. They may also serve as a means to introduce a new staple food into a cuisine by making it taste familiar with the traditional flavor principle (E. Rozin & Rozin, 1981).

The meal is another component of cuisine. Meals have an internal structure, varying from a single dish of combined ingredients to sequences of foods, as in the appetizer–entrée–dessert sequence common in many Western cuisines (see Douglas & Nicod, 1974, for an analysis of the British meal). In many traditional cultures, the various meals are similar in content and structure, with breakfast as warmed over dinner. In many Western cultures, a separate first meal, breakfast, has its own foods and flavors. Howard Schutz (1989) has pointed out that cultures’ “appropriateness” rules have to do with what foods can be mixed or eaten together, proper sequences of foods, and foods for particular times or occasions.

The social eating situation is a third aspect of cuisine. There are issues of who eats with whom, order of eating (e.g., children first), and rules for leaving the table and for what is supposed to be discussed during the meal. These very elaborate traditions are treated in the next section.

CIVILIZED EATING

One of the most striking things about the food world that varies a great deal across cultures is the etiquette of eating, or table manners. As Kass (1994) and Elias (1939/1978) point out, the meal is one of the special areas in which humans display and celebrate the fact that they are civilized. Most modern humans do not eat like animals. They sit at tables, use utensils, respect and do not touch the food on the plates of

others, refrain from calling attention to their bodily functions while eating, and observe complex rules of social interaction. Civilized eating is highly complex and requires great skill. Both Kass and Elias indicate that in civilized eating, the biological aspects of eating are suppressed (see the earlier discussion of suppression of disgust during eating). The learning of table manners by children is surely one of the more difficult aspects of growing up.

All of these civilizations of the daily meal are yet more elaborated in the special food occasions, such as attending restaurants, feasts, dinner parties, or weddings (Kass, 1994). And the etiquette and subtle meanings of eatings are particularly elaborated in Hindu–Indian culture (Khare, 1976).

FOOD SOCIALIZATION: WEANING AND TOILET TRAINING

With breast-feeding and careful monitoring of the human infant by its mother, little can go wrong with its food world in the first year. Evidence suggests that for the first year or two of life, children will put anything they find into their mouth (P. Rozin, Hammer, et al., 1986). This potentially dangerous tendency is neutralized by maternal vigilance. It seems that the most important thing a child has to learn in the early years is what *not* to eat. Of course, in addition to familial vigilance, the environment can be scoured so that the child does not encounter dangerous things.

Freud correctly noted two of the major events of early childhood: weaning and toilet training. One is about food, and the other is a consequence of eating. Weaning is a necessary event, and toilet training, though not literally necessary, is universal. Both involve denying a child a pleasure, and both can be problematic. Both are problems solved in very diverse ways in different cultures, at different ages, with different degrees of attention and harshness. Because Freud saw these two events as central in the formation of personality, they received great attention in a cross-cultural context for at least a generation of field anthropology. As with many other features of a highly overdetermined developmental trajectory, normal children can and do typically become trained following a wide range of weaning and toilet training procedures. These are things that have to be done, but how they are done is not

highly constrained in terms of much higher benefits or costs for one technique as opposed to another. Indeed, a related issue, bottle- or breast-feeding, has occupied an enormous amount of research attention in psychological and medical research in the developed world.

The most important aspects of both toilet training and weaning is that they demand attention, are usually taken seriously by adults, and are accomplished in accordance with a rather complex set of belief structures and practices. They are about food and are major milestones in early life. Ironically, no doubt in part due to the attention they received by Freud, developmental psychology in the last part of the 20th century paid scant attention to these two fundamental processes (P. Rozin, *in press*).

The acquisition of table manners and food traditions is another important aspect of food socialization that has been little studied by psychologists. Birch, Billman, and Richards (1984) reported that the category of special foods eaten at breakfast in the United States becomes distinctive and separate for children in the later preschool years. P. Rozin, Fallon, and Augustoni-Ziskind (1986) reported that until the later preschool years, children in the United States do not understand or incorporate a variety of food-mixing prohibitions; thus, the young preschool child who likes food A (e.g., steak) and food B (e.g., ice cream) will like A + B. Cuisine is not that simple (Schutz, 1989).

PREFERENCES: FORMATION AND TRANSMISSION

Food is one of the domains in which preferences are salient. Most foods are either liked or disliked; relatively few produce a neutral response. It is quite remarkable that although preferences for food, music, and a wide range of activities are a very important part of life (and economics), they are studied little by psychologists, cultural or otherwise (P. Rozin, *in press*). The question for all preferences (leaving aside love and preferences for other people) is, how do they get formed? What makes us like some things and dislike others? The food domain is a natural place to study this, because there are so many food preferences, they are public, and they are usually open for discussion (e.g., unlike sexual preferences). Surely, one of the major distinctive features of a culture is its cuisine and associated food preferences. If we

know someone is particularly fond of rice and soy sauce, we can make a good guess that they are from East or Southeast Asia.

Whereas there are surely large cross-cultural differences in food preferences, there is also wide variation within cultures. There is no point in trying to quantify and compare these differences; it all depends on which foods are being studied. Variance in preference for tofu is going to be largely intercultural between Chinese and Americans. But, for the same two cultures, variance in preferences for broccoli might well be primarily explained intraculturally.

Given the generalist background of humans, it is unlikely that most preferences are accounted for in terms of genetic endowment. Two other natural reasons might be critical early experiences and the early environment, as controlled and instantiated largely by the parents. Of course, the human mammal would be poorly served by a tendency to develop strong and permanent preferences for early foods. This would have led to a focus on milk, a food unavailable in the ancestral environment after weaning. That adult food preferences are largely formed in the first 6 years of life is a common Western view, perhaps a derivative of Freud's focus on what he designated the critical first 6 years. So far as I know, there is no evidence that the first 6 years are any more important than the next, or the next 6 years after that.

Both genetic and early experience accounts predict substantial parent-child correlations in food preferences. Remarkably, they are in fact very low. Results from Americans suggest values averaging around .15 for preferences for specific foods, comparing the preferences of parents (or the midpoint of mother and father) and the preference of their adult child (Pliner, 1983; P. Rozin, 1991). Similar results appear for music preference, whereas correlations for values such as attitudes to abortion are notably higher (P. Rozin, 1991). Cavalli-Sforza, Feldman, Chen, and Dornbusch (1982) identified three routes for transmission of preferences: vertical (parent-child), horizontal (peer influence), and oblique (e.g., teacher-student, media-child). The low parent-child correlations suggest substantial roles for peers, teachers, heroes, and culturewide forces.

It is not surprising that parents, peers, and other cultural forces produce certain within-culture commonalities in preferences. Not at all

clear is what produces within-culture differences. We do not have a set of well-documented mechanisms, although mere exposure (Zajonc, 1968; Pliner, 1982), some types of evaluative conditioning (Martin & Levey, 1978; deHouwer, Thomas, & Baeyens, 2001), and “social influence” (whatever that means; e.g., Birch (1980); Birch, Zimmerman, & Hind, 1980; Baeyens et al., 1996; Duncker, 1938) are surely involved (for reviews, see Birch, Fisher, & Grimm-Thomas, 1996; P. Rozin, 1988, 1990b).

Peer influences are obviously important in the development of food preferences in some cultures, perhaps especially in adolescence. There is some surprising evidence of its absence in food and music preferences in some American contexts (Rozin, Riklis, & Margolis, 2003).

Of course there is more to transmission than preference. Attitudes toward food and eating, including their importance in comparison to other activities, and the balance of worries and pleasures about eating vary considerably not only between cultures (e.g., between France and the United States; P. Rozin, Fischler, Imada, Sarubin, & Wrzesniewski, 1999) but also within cultures. Recent ethnographic data suggest that some of the major differences in food attitudes between Americans and Southern Europeans can be traced to differences in the types of interactions that occur around the dinner table (Ochs, Pontecorvo, & Fasulo, 1996). The Italian family eating environment is much more oriented toward the shared pleasure of eating, and less toward concerns about food, health, and coaxing children or making bargains to promote healthier eating. This work is a promising beginning for systematic studies of food socialization in a cultural context.

THE INVERSION OF THE ANCESTRAL FOOD WORLD AND THE OBESITY EPIDEMIC

A particular problem of general interest to cultural psychology and cultural studies has to do with the stresses and dislocations that occur in human life as a result of major and rapid culture advances, especially in technology. For example, the rapid increase in the power and accessibility of the Internet and e-mail have produced much more rapid and widespread links among people around the world, allowing a rumor to spread around the world in hours,

as opposed to years. Although most news that individuals received was vetted through a chain of other people or, more recently, newspapers and other media, an individual can now spread “news,” accurate or not, directly to consumers around the world. Modern societies have yet to figure out how to compensate for the potential dangers of instant communication and rapid transmission of diseases because of extensive international travel, or how to control weapons of mass destruction.

We are, both biologically and culturally, adapted more to our ancestral food environment than to our very recent, developed world cultural environment. Enormous challenges to humans have emerged in the food domain as a result of technological advances. The inversions are laid out in Table 16.2. An ancestral environment in which food was in relatively short supply has been replaced by an environment in which cheap food is abundant and always available. An ancestral environment that offered a modest variety of potential foods, mixed with many acutely dangerous potential foods, has been replaced by an environment offering an extraordinary range of safe food choices; I venture that the contemporary urban food supermarket has more different types of foods available than were ever available to anyone on earth even 30 years ago! In the ancestral environment, the foods available evolved under complex adaptation pressures and were rarely (except for animal foods) very calorie dense; in the contemporary environment, foods of extraordinary caloric density and extraordinarily appealing sensory properties are available; chocolate is a prime example. There is nothing so palatable or calorie dense in the natural plant world. In the ancestral environment, we had to work to obtain food; in the contemporary environment, minimal calorie expenditure is necessary. In the ancestral environment, there was a rather close temporal link (measured usually in hours) between ingestion of a food and appreciation of its consequences (nutritional virtues or toxicity).

In the contemporary environment, acute risks of imbalance or toxicity are minimized by cultural means, such as sanitation systems and preservatives. The generally remote food risks in contemporary developed cultures are described as consequences for life expectancy that result from particular patterns of food choice; these are measured in decades, not in hours. The epidemiological revolution is largely re-

TABLE 16.2. Contrast between Human Ancestral Food Environment and Contemporary Developed World Food Environment

Feature	Ancestral environment	Contemporary developed world environment
Availability	Modestly short supply	Wildly abundant
Variety	Modest	Extraordinary: almost all edibles and cultural elaborations of them available to everyone
Super foods	Nonexistent, except for animal foods	Widely available via technological advance (e.g., grain flours, chocolate)
Energy expenditure necessary to obtain food	Substantial	Minimal
Cost	Substantial in terms of time and energy expenditure	Minimal
Consequences of foods: Epidemiological revolution	Apparent within hours of ingestion	Not apparent at all, culturally informed re: effects decades later
Suitability for evaluating foods	Adapted to short-term consequence evaluation	Inability to process and understand complex long term food risk information

sponsible for this change. Only in the contemporary environment do we get information in the form of risk or probabilities of the long-term effects of dietary patterns from epidemiological and other cultural resources. But we are not evolved to make this sort of evaluation; we did not originally live that long, and the short-term effects of foods were our predominant concern. Cultures have yet to adapt to this source of information. Individuals are not educated about even the basics of probability or the nature of science, and are unable to evaluate the importance of communicated information about risks. Hence, the cultural transformations that occurred largely in the 20th century have rendered our biological heritage, finely tuned to our ancestral environment, worse than useless. And the technological advances (e.g., in epidemiology) have not been compensated by lay education that would allow us to comprehend them and behave adaptively with respect to them; we do not teach nutrition, probability, and associated risk–benefit analysis, and we do not teach how science works, which would allow individuals to interpret intelligently the findings of specific studies broadcast in the media.

The result of these mismatches has been an “epidemic” of obesity and widespread dieting, and concern about eating a healthy diet. It is our biological heritage—and that of most if not all animals—to expend as little energy as possible to obtain adequate nutrition and protec-

tion, because energy expenditure requires more energy intake, which itself consumes energy and increases the probability of being prey for other species (Elner & Hughes, 1978; Krebs & Davies, 1997). Furthermore, in the natural world, there is generally a bias to consume food when it is available, since it is often scarce, and undernutrition is a greater threat than overnutrition. Our biological tendencies to eat when food is available and to expend as little energy as possible have become destructive in the modern developed world, where food is palatable, plentiful, and available with minimal energy expenditure.

One result of all of these forces, particularly in the United States, is a great ambivalence about eating, with concerns about obesity tempering the potential enjoyment of a highly palatable, omnipresent, and inexpensive food world (Rodin, Silberstein, & Striegel-Moore, 1985; P. Rozin, Bauer, & Catanese, 2003).

My French colleague Claude Fischler and I, along with a number of students, have taken on the task of examining how different cultures deal with the mismatch between the ancestral and contemporary, developed world food environment, focusing on France and the United States. We have argued that France has been more successful in creating or maintaining compensatory cultural institutions (P. Rozin, Fischler, et al., 1999; P. Rozin, Kabnick, Pete, Fischler, & Shields, 2003; summarized in P. Rozin, 2005), because traditional features of

cultural food-related and other institutions in France offer a better buffer to the changes in the food environment. The evidence for greater success in France is not only the substantially lower level of obesity and overweight in France but also a much lower incidence of death due to cardiovascular disease. Our observations and measurements suggest that the French situation is more successful than the American one of the following reasons:

1. The French food environment discourages overeating by offering smaller portions and discouraging snacking (P. Rozin, Kabnick, et al., 2003).
2. The cultural geography of living styles in France, including especially the availability of food sources (stores) locally and within walking distance of most homes, and the greater inconveniences and expenses associated with the use of automobiles, probably leads to greater energy expenditure in daily life in France.
3. The traditional French attitudes toward food focus more on the experience of eating and less on the (health) consequences of eating, leading to less conflict and worry about eating, and more pleasure.
4. Certain deep differences in cultural values with respect to food tend to reduce the impact of easy availability of inexpensive, varied, and highly palatable foods (Stearns, 1997; P. Rozin, 2005). These cultural values include:
 - a. An emphasis on moderation as the reigning principle for eating in France, as opposed to abundance in the United States. The striking contrast is illustrated by the quintessential American eating holiday, Thanksgiving, in which being overstuffed seems to be a sign of a successful dinner. As well, the “all you can eat” restaurant is common in the United States and rare in France (P. Rozin, Kabnick, et al., 2003).
 - b. A related emphasis on food quality in France and food quantity in the United States. In a sense, love and caring are expressed more in terms of quantity of food offered in the United States versus quality of food in France.
 - c. Collective food values are more prominent in France, whereas individualized food values are prominent in the United

States. This may result from the strong individualism/Protestant traditions in the United States. As a result, Americans prefer to be offered a much wider variety of minor variants of the same food (Rozin, Fischler, Shields, & Masson, 2006), and are much more inclined in a restaurant to do their own mixing and matching of main meat dish and vegetable accompaniments, and more individualized seasoning of foods (salt, pepper, ketchup, mustard, etc.).

- d. Americans are more motivated to spend money and arrange their lives to minimize effort and maximize convenience, which has the result of spending less energy. The French are more inclined to spend more money on maximizing joy, that is, having memorable and relatively unique experiences. This corresponds to the important distinction between comforts and pleasures made by Scitovsky (1976/1992).
- e. Americans are more inclined to conceive of health as heavily influenced by environmental influences (e.g., electric power lines, environmental toxins, foods), whereas the French see health more as a matter of internal balance (Payer, 1996).

In short, our analysis indicates that the greater success of the French in resisting both the promotion of overeating and inactivity in the modern world results from a combination of differences in cultural values and in the arrangement of the environment. Most of the differences described here operate to preserve the pleasures of eating, reduce exaggerated worries about eating, and promote weight control in the French as opposed to Americans. It is not that the French have developed better compensatory mechanisms for the modern food environment, but that food institutions already in place have increased resistance to these changes.

FOOD AND SEX

I have argued that food plays a special role in cultural psychology because of the ways cultures have transformed the food domain. In contrast, sex plays a prominent role in evolutionary psychology, because of the many basic

similarities in the construal and contexts of sexual behavior in the ancestral and modern environments. Yet there are important and fundamental similarities between these two domains. From the point of view of behavior, food is the critical domain for individual survival, and sex, for species survival. Both are incorporative; except for breathing, these are the two domains in which we take into our bodies material substances from outside our bodies. In both domains, there is great sensitivity about what gets in; there is great pleasure when the “right” stuff gets in, and great aversion, fear, and disgust when the “wrong” stuff gets in.

Contamination and purity are important in the thinking within both domains. Both sex and food involve sharing substance with another person. This is obvious for sex (and may include shared saliva). For food, shared substance occurs in three senses: eating a food prepared by another person, and eating together with another person (perhaps from the same plate or taking bites from the same entity) and, in societies that practice cannibalism, eating another person—either as a demeaning act (analogous to rape) or as an intimate, incorporative act of preserving a loved one within oneself. Alan Fiske (personal communication, January 16, 1991) has pointed out that eating is commonly used as a metaphor for sexual relations in many cultures, and that rules concerning food and sex are often either parallel or mutually determinative. For example, South Asians of higher caste abhor sharing food or drink with people of lower caste and women having sexual relations with men of lower caste. For men in some West African cultures, it is taboo to eat, drink, or share tobacco or kola with the husband of any woman with whom they have sex. They believe that to do so would kill the husband. Conversely, a woman must never cook food for a man who eats with another man with whom she has sexual relations. In several West African pastoralist societies, warriors have sexual relations with some women and eat food cooked by others, but they cannot be seen eating by the women with whom they have sex. In Western cultures, dinner dates and patterns of food sharing may be considered part of sexual foreplay.

Meigs's (1984) analysis of the food taboos of the Hua of Papua New Guinea is an exemplary demonstration of mixed nutritive and sexual meanings of foods. Foods are believed to be ve-

hicles for “vital essence,” deriving from both their origins and the people who have handled them. There is great concern that pubescent males be protected from feminization by foods. Hence, they are not allowed to consume any food raised or prepared by a fertile woman. Furthermore, a whole set of foods that are believed to be feminine, and hence feminizing, are prohibited during this period. Meigs assembled a list of such foods, and noted that, as a group, they are reddish in color and soft in texture.

Sex and food each have their relevant aperture, though the mouth is, in many cultures, shared in both food and sex functions. Parallels between the vagina and the mouth are obvious, including common terminology (labia and lips). The high sensitivity of women to vaginal intrusion by foreign and potentially contaminating objects parallels the sense of oral intrusion for such objects by both males and females (P. Rozin, Nemeroff, Horowitz, Gordon, & Voet, 1995).

Finally, at least in American English, there are important metaphorical exchanges of food and sex words. *Eat* has sexual connotations; the word *meat* is sometimes used to refer to women in a sexual context and is also used to refer to male genitals.

SOME IMPORTANT GENERAL ISSUES THAT CAN BE WELL-ADDRESSED IN THE FOOD DOMAIN

Many basic issues in psychology are present in both food and other domains. In some cases, the food domain may provide a particularly convenient area for study of such issues; in other cases, insights from the study of food and eating may contribute to general understanding, or greater understanding of another domain of life. A few of these general issues are considered here.

Food and Environment

The amount of food consumed, and the choice of food are both influenced by many factors, some of which fall within the domains of physiology, psychology, and culture. Perhaps the single most important determinant, mundane as it may be, is the environment. One can only eat foods that are available in the environment. Generally, if food is accessible and at least mildly palatable, people will eat it. The availability of food is principally a result of eco-

conomic factors and sociocultural traditions and institutions. The previous analysis of the “French paradox” suggests a major role for differences in the physical and social environments of the United States and France. The idea that people eat what is available does not excite the imagination, nor does it encourage psychological theory. That it has not been given much attention in the psychological study of food and eating is perhaps a manifestation of a “fundamental attribution error.” In most psychological studies, what is at issue, given the presence of food or food choices, is how people think and behave. But recent work on food, much from within psychology, has focused on the environment, particularly portion size as a main determinant of food intake. A number of investigators have pointed this out in recent years (Hill & Peters, 1998; Rolls, 2003; P. Rozin, Kabnick, et al., 2003; Wansink, 2004), and have documented cultural differences in this area (Rozin, Kabnick, et al., 2003) and recent American historical trends toward larger portion size (Rolls, 2003; Young & Nestle, 1995). Portion size, and more general issues of food availability and context (Meiselman, 1996), fall heavily into the domain of cultural psychology.

Food, Social Class, and Social Structure

The foods consumed, and attitudes toward food, vary across social classes. This area represents an interface between psychology and sociology. Cultural psychology must address social structure and social class, because these are psychologically important manifestations of culture. The social structure of Hindu India has an enormous influence on food transactions, as mediated by the caste system (Appadurai, 1981; Marriott, 1968). Changes in food habits within any culture usually take place over decades or even centuries, and typically move from one class to another. Thus, for example, in Europe, chocolate moved from upper to lower classes. Economic factors (rarity and high cost) partly account for this, as well as a general tendency for lower classes to imitate the behavior of higher classes. On the other hand, some foods, including chili pepper and, more generally, highly spiced foods, have often moved from the lower to the upper classes. The popularity of ethnic cuisines among well-off Americans in recent decades represents a movement from lower to higher classes.

Finally, in modern American society, principally among more educated and wealthy groups (Leichter, 1997), the idea of healthy eating and exercise has taken hold. This often acquires a moral tinge, what has been called “secular” morality by Solomon Katz (1997).

Food as Symbol

Symbolism has always held a fascination in psychology, partly because both metaphors and symbols seem such a central part of human life (e.g., Lakoff & Johnson, 1980). Food, because of its centrality in life, and because it is incorporated into the body, is a major source for symbols and metaphors. For example, rice plays a central role in Japanese life and thought, over and above its nutritional importance (Ohnuki-Tierney, 1993). Food is at the center of many taboos, many of which seem to serve functions outside the domain of nutrition (e.g., Douglas, 1966).

Globalization and Starvation

An important general issue that is well illustrated in the food domain is globalization. Technological advances and globalization have made calories inexpensive (Drewnowski, 1999), have led to a market that caters precisely to individual tastes (Kahn & McAlister, 1997), and have generally transformed the world of food and nutrition (Sobal, 1999). What used to be local food risks have become well-publicized, international fears, with mad cow disease as a clear example (Fischler, 1999). Modern food technology and the modern car-based environment has fostered a situation in which convenience has become a prime commodity. It is likely that the inherent and biologically predisposed laziness of all animals, including humans, is being catered to more and more effectively. It may soon be possible to accomplish eating, entertainment, and other major activities with a minimal of energy expenditure. It was once good to be lazy, but it may not be any more, in terms of either quality of life or longevity. In the meantime, technological advances have greatly improved the safety and shelf-life of foods, introduced a massive variety of highly palatable foods, cut food prices, and made it easy to deliver any type of food almost anywhere in the world. Food is a major area for the study of globalization. The successful penetration of McDonald's into vastly different

cultures argues for both important food universals, and a certain cultural sensitivity motivated by the profit motive (Watson, 1997).

At the same time that all of this is happening, along with the surplus of cheap and nutritive food in the developed world, there are still major problems with starvation in the less developed world. It is generally agreed that starvation is a complex product of politics, and economics, sometimes exacerbated by specific cultural practices or preferences. But the major problem today seems to be one of distribution of already produced food to the locations where it is most needed, and this has to do with economics, politics, and culture.

CONCLUSIONS

Food is basic, and it is about biology, psychology (individual experience), and culture. There are many universals and many major culture differences. Cultural evolution is particularly robust in the food domain, and preadaptation of foundational food system features is rampant. The food system presents particular challenges and particular opportunities for cultural psychology. The cross-cultural and historical records are good, especially because food is so central in archeology and ethnography. The biological constraints and predispositions are well understood. What we need is for more researchers to take up the challenge.

CHAPTER 17

Religion's Social and Cognitive Landscape

An Evolutionary Perspective

SCOTT ATRAN

Le XXIème siècle sera religieux ou ne sera pas
[The 21st century will be religious or will not *be*].
—ANDRÉ MALRAUX

This chapter explores religion's social and cognitive landscape from an evolutionary perspective. Explaining religion is a serious problem for any evolutionary account of human thought and society. Religious practice is costly in terms of material sacrifice (at least one's prayer time), emotional expenditure (inciting fears and hopes), and cognitive effort (maintaining both factual and counterintuitive networks of beliefs). Adaptationist arguments usually attempt to offset the apparent functional disadvantages of religion with even greater functional advantages, such as maintenance of personal well-being and group solidarity.

The main thesis in this chapter, however, is that religion is not an evolutionary adaptation *per se*, but a recurring *by-product* of the complex evolutionary landscape that sets cognitive, emotional, and material conditions for ordinary human interactions. The conceptual foundations of religion are intuitively given by task-specific, panhuman cognitive domains, including folk mechanics, folk biology, and folk psychology. Core religious beliefs minimally violate ordinary intuitions about the world, with its inescapable problems. Cultural manipulations of humans' innate hypersensitivity to agency in folk psychology are especially important for understanding the supernatural. Be-

cause supernatural beliefs minimally violate and readily activate intuitively given modular processes, they are more likely to survive transmission across minds under a wide range of different environments and learning conditions, and to become recurrent and enduring aspects of human cultures. Because religious beliefs cannot be deductively or inductively validated, validation occurs only by ritually addressing the very emotions motivating religion, although ritual modes may differ appreciably in literate and large-scale societies versus small-scale societies that rely more heavily on iconic representations and face-to-face contact.

Enabling people to imagine minimally impossible supernatural worlds helps to solve existential problems, including death and deception. In the competition for moral allegiance, secular ideologies are at a disadvantage. For if people learn that all apparent commitment is self-interested convenience or worse, manipulation for the self-interest of others, then their commitment is debased and withers. Noninstrumental or “sacred” values appear to rouse hearts and minds passionately to break out of this viciously rational cycle of self-interest, and to adopt group interests that may benefit individuals in the long run, though compulsory adherence to such values can also encourage cultural intolerance and protracted political conflict.

INTRODUCTION

Ever since Edward Gibbon’s (1845/1776) *Decline and Fall of the Roman Empire*, scientists and secularly minded scholars have been predicting, or pushing for, the ultimate demise of religion (cf. Dawkins, 2006; Dennett, 2006; Harris, 2006). But, if anything, religious fervor is increasing across the globe. New religious movements (NRMs) continue to arise at a furious pace—perhaps at the rate of two or three per day (Lester, 2002). There are now nearly 2 billion self-proclaimed Christians (about one-third of humanity), 25% of whom are Pentecostals or charismatics (people who stay in mainstream Protestant and Catholic churches and have adopted Pentecostal practices, e.g., healings, speaking in tongues, casting out demons and laying hands upon the sick; Goodstein, 2000, p. 24). In Africa, for example, the Winner’s Church, a Pentecostal church

that celebrates newfound market wealth and success, is only a dozen years old (N. Onishi, 2002) but already has more than 50,000 members in 32 branches on the continent. During the same period, the Falun Gong, a Buddhist offshoot, has grown to perhaps 100 million adherents in East Asia and the Al Qaeda-led *jihadi* movement has spread across the Muslim world.

The United States—the world’s most economically powerful and scientifically advanced society—is also one of the world’s most professedly religious societies. Evangelical Christians and fundamentalists include about 25% of Americans (Talbot, 2000, p. 36) who, together with charismatics, comprise about 40% of the American population. About the same number believe that God speaks to them directly (H. Bloom, 1999, pp. 120–123). Among Americans, 90% pray for God’s intervention in life and 90% believe God cares for them (H. Bloom, 1999); 69% believe in angels, and at least 50% believe in ghosts, the devil, and the literal interpretation of Genesis (polls cited in Pinker, 1997; Dennett, 1995). Even in Western Europe, the most secular of societies, more than 60% of the population believe in the soul (Humphrey, 1995).

An underlying reason for religion’s endurance is that science treats humans and intentions only as incidental elements in the universe, whereas for religion they are central. Science is not particularly well-suited to deal with people’s existential anxieties—death, deception, sudden catastrophe, loneliness, or longing for love or justice. It cannot tell us what we *ought* to do, only what we can do. Religion thrives because it addresses people’s yearnings and society’s moral needs. Other factors in religion’s persistence as humankind’s provisional evolutionary destiny involve naturally selected elements of human cognition. These include the inherent susceptibility of religious beliefs to modularized (innate, universal, domain-specific) conceptual processing systems, such as folk psychology, that favor survival and recurrence of the supernatural within and across minds and societies.

Although science may never replace religion, science can help us understand how religions are structured in individual minds (brains) and across societies (cultures), and also, in a strictly material sense, why religious belief endures. In every society,¹ it appears, there are the following:

1. Widespread counterfactual and counter-intuitive belief in supernatural agents (gods, ghosts, goblins, etc.).
2. Hard-to-fake public expressions of costly material commitments to supernatural agents, that is, offering and sacrifice (offerings of goods, property, time, life).
3. Mastery by supernatural agents of people's existential anxieties (death, deception, disease, catastrophe, pain, loneliness, injustice, want, loss).
4. Ritualized, rhythmic sensory coordination of items 1, 2, and 3, that is, communion (congregation, intimate fellowship, etc.).

In all societies an evolutionary canalization and convergence of items 1, 2, 3, and 4 tends toward what I refer to as “religion”; that is, passionate communal displays of costly commitments to counterintuitive worlds governed by supernatural agents (Atran, 2002). Although these facets of religion emerge in all known cultures and animate the majority of individual human beings in the world, there are considerable individual and cultural differences in the degree of religious commitment. (But an analysis of the origin and nature of these intriguing and important differences must be left for another time.)

These four conditions do not constitute necessary and sufficient features of “religion.” Rather, they comprise a stipulative (working) framework that delimits a causally interconnected set of pancultural phenomena that comprises the object of our study (Atran & Norenzayan, 2004). One may choose to call phenomena that fall under this set of conditions “religion” or not; however, for my purposes their joint satisfaction is what I mean by the term. Nevertheless, this working framework is offered as an adequate conceptualization that roughly corresponds to what most scholars consider religion.

Cognitive theories of religion primarily concern item 1. These concentrate almost entirely on the micropsychological processes of cultural transmission, the processes that causally generate, transform, and connect chains of mental and public representations into “cultures,” and parts of culture such as religion. Cognitive theories attempt to explain religious belief and practice as cultural manipulations of ordinary psychological processes of categorization, reasoning, and remembering (Sperber, 1975;

Atran, 1990; Lawson & McCauley, 1990; Boyer, 1994; Andresen, 2001; Pyysiäinen & Anttonen, 2002). Empirical studies in this area have almost wholly concerned memory and cognitive constraints on the structuration and transmission of religious beliefs (J. Barrett & Keil, 1996; Barrett & Nyhoff, 2001; Boyer & Ramble, 2001; Owsianiecki, Upal, Sloan, & Tweney, 2005). They do not account for the emotional involvement that leads people to sacrifice to others what is dear to themselves, including labor, limb, and life. Such theories are often short on motive and unable to distinguish Mickey Mouse from Moses, cartoon fantasy from religious belief (Atran, 1998, p. 602; cf. Boyer, 2000). They fail to tell us why, in general, the greater the sacrifice of personal self-interest for apparently absurd group beliefs—as in Abraham offering up his beloved son to an invisible being—the more others trust in one's religious commitment (Kierkegaard, 1843/1955).

Commitment theories of religion primarily concern item 2. These focus almost exclusively on the macroinstitutional dynamics of socially distributed traits, rules, norms, and other cultural prototypes. Commitment theories attempt to explain the apparent altruism and emotional sacrifice of immediate self-interest accompanying religion in terms of long-term benefits to the individual (Alexander, 1987; Irons, 1996; Nesse, 2001) or group (Boehm, 1999; Sober & Wilson, 1998; D. S. Wilson, 2002; Boyd & Richerson, 2005)—benefits that supposedly contribute to genetic fitness or cultural survival. Empirical studies have almost wholly concentrated on material measures of individual and group costs and benefits. They do not account for the cognitive peculiarity of the culturally universal belief in beings who are imperceptible in principle, and who change the world via causes that are materially and logically inscrutable in principle. They do not distinguish Marxism from monotheism, secular ideologies from religious belief.

Experiential theories primarily concern item 3. These mainly target states of altered consciousness and personal sensations. Empirical studies focus on tracking participants' neurophysiological responses during episodes of religious experience and recording individual reports of trance, meditation, vision, revelation, and the like (Persinger, 1987; Beit-Hallahmi & Argyle, 1997; d'Aquili & Newberg, 1999; Jo-

seph, 2002). Cognitive structures of the human mind/brain in general, and cognitions of agency in particular, are described either cognitively in simpleminded terms (binary oppositions, holistic vs. analytical tensions, hierarchical organization, etc.) or in psychoanalytic terms that have little input from, or pertinence to, recent findings of cognitive and developmental psychology.

Performance theories primarily concern item 4. These attend to the psychosocial dynamics of liturgy and ritual practice, that is, to the affective character and sociological implications of what Durkheim (1912/1995) called “collective effervescence.” Empirical studies have almost wholly focused on normative and ceremonial expressions of religion. They underplay more mundane cognitive processes of categorization, reasoning, and decision making that underlie all religious beliefs and commitments, and that make such beliefs and commitments comprehensible (Barth, 1975; V. Turner, 1969; Tambiah, 1981; Rappaport, 1999; Watanabee & Smuts, 1999).

Now, if (1) supernatural agents are cognitively salient, and possess omniscient and omnipotent powers, and (2) there is sufficient costly signaling from people within a community to convince others that commitment to the supernatural is genuine, then (3) the supernatural can be invoked to ease existential anxieties, such as death and deception, that forever threaten human life everywhere and from which no enduring rational escape is possible. However, conceptions of the supernatural invariably involve the interruption or violation of universal cognitive principles that govern ordinary human perception and understanding of the everyday world. Consequently, religious beliefs and experiences cannot be reliably validated (or disconfirmed as false) through consistent logical deduction or consistent empirical induction.

Validation occurs only by (4) collectively satisfying the emotions that motivate religion in the first place. Through a “collective effervescence” (Durkheim, 1912/1995), communal rituals rhythmically coordinate emotional validation of, and commitment to, moral truths in worlds governed by supernatural agents. Through the sensory pageantry of movement, sound, smell, touch, and sight, religious rituals affectively coordinate actors’ minds and bodies into convergent expressions of public sentiment (cf. Tinbergen, 1951)—a sort of *N*-person

bonding that communicates moral consensus as sacred, transcending all reason and doubt (Rappaport, 1999). But for those left outside the religious consensus, it may seem that “cruelty and intolerance to those who do not belong to it are natural to every religion” (Freud, 1921/1955).

The rituals that accompany all religions almost always include music and other sorts of voluntary rhythmic stimulations. Even the Taliban, which banned nearly every sort of collective sensory stimulation, systematically used *a capella* chants to cement adherence to their religious fraternity.² Prayers in all religions employ the same gestures of submission: outstretched arms with chest exposed and throat bared, genuflection, prostration, and so on. These are pretty much the same bodily expressions that other social animals display to signal submission, including our simian cousins and canine friends. But for humans such gestures are not merely symbolic: In embodying them people actually provoke in themselves feelings of submission and humbleness before a greater power. Other common ritual acts that socially coordinate bodily movements among members of a congregation include sway and dance. The emotional unity created during these performances underscores the commitment to sacrifice a bit of oneself for others—not necessarily in the here and now, but as an open-ended promise to help others in any number of ways when they may need it most.

To evoke a strong and intimate sense of community, members of a religious community often create families of fictive kin. For example, from Paris suburbs to Indonesian jungles, the Mujahedin I have interviewed who profess religious commitment to martyrdom actions (suicide attacks) come from almost every walk of life and socioeconomic background (which is why global profiling across cells of suicide bombers is a waste of time); however, within each cell of typically 8–12 people, all tend to eat the same sort of food, sport the same clothing, chant the same slogans, and share the same daily rites and routines. Through incorporation of recruits into relatively small and closed cells—emotionally tight-knit brotherhoods—religiously inspired terror organizations create a family of cellmates who are just as willing to sacrifice for one another as is a parent for a child. These culturally contrived cell loyalties mimic and (at least temporarily) override ge-

netically based fidelities to kin, while securing belief in sacrifice to a larger group cause. And this can even mutate over the Internet into a virtual family whose members may be physically remote from one another, but who are as emotionally linked and primed for mutual sacrifice as any real family or group of friends (Atran & Stern, 2005).³

In the final tally, eruptive emotions are often stronger and more convincing than careful reason—perhaps because evolution selected our emotions to wax when we believe ourselves to be faced with inescapable problems of survival. Failure to figure in the emotional costs and payoffs associated with those aspects of life that are not rationally controllable—including death and deception, heartbreak and loneliness, catastrophe and want, injustice and lack of fairness—reduces any purely cognitive theory of religion to barely more than an account of how people are able to assimilate all manner of fictional reverie.

WHY IS RELIGION AN EVOLUTIONARY DILEMMA?

Religion is a serious riddle for any evolutionary account of human thought and society. From an evolutionary standpoint, the reasons for why religion should not exist are patent: Religion is materially expensive, and it is unrelentingly counterfactual and even counterintuitive. Religious practice is costly in terms of material sacrifice (at least one's prayer time), emotional expenditure (inciting fears and hopes), and cognitive effort (maintaining both factual and counterintuitive networks of beliefs). Summing up the anthropological literature on religious offerings, Raymond Firth (1963, pp. 13–16) concludes that "sacrifice is giving something up at a cost. . . . 'afford it or not,' the attitude seems to be."⁴

In all religions, argued the empirical philosopher and religious believer Thomas Hobbes, there are bodiless but sentient souls and spirits that act intentionally, though not in ways that can be verified empirically or understood logically. As for "one infinite, omnipotent, and eternal God," even the enlightened "choose rather to confess He is incomprehensible and above their understanding than to define His nature by 'spirit incorporeal,' and then confess their definition to be unintelligible" (1651/1901, Vol. 1, part XII, p. 69). (This "incompre-

hensibility" is strongly related to the technical notion of "counterintuitiveness" that I discuss a bit later on.)

If people literally applied counterfactual and counterintuitive religious principles and prescriptions to factual navigation of everyday environments they would likely be either dead or in the afterlife in very short order—probably in too short order for individuals to reproduce and the species to survive. Imagine creatures who always truly believed that the dead lived on and the meek were advantaged over the strong, or that one could arbitrarily suspend the known physical and biological laws of the universe with a prayer (or for those less institutionalized, by crossing one's fingers). Their fitness value would be close to nil. The trick is in knowing how and when to suspend factual belief without countermanding the facts and compromising survival. But why take the risk of neglecting the facts at all, even in exceptional circumstances?

As for costly material commitment to the supernatural, there cannot be individual fitness advantages of the sort that part-for-whole sacrifice among animals may convey (Burkert, 1996) given that the probability of certifiably obtaining the desired outcome, such as a rewarding afterlife or freedom from catastrophe, ranges between zero and chance. For a bear to sacrifice its paw in a trap by gnawing it off, a lizard to leave behind its tail for a predator, or a bee to die by stinging an intruder to save the hive, seem reasonable trade-offs for survival. Yet what could be the calculated gain from the following:

- Years of toil to build gigantic structures that house only dead bones (Egyptian, Mesoamerican, and Cambodian pyramids)?
- Giving up one's sheep (Hebrews) or camels (Bedouin) or cows (Nuer of Sudan) or chickens (Highland Maya) or pigs (Melanesian tribes, Ancient Greeks), or buffaloes (South Indian tribes)?
- Dispatching wives when husbands die (Hindus, Incas, Solomon Islanders)?
- Slaying one's own healthy and desired offspring (the first born of Phoenicia and Carthage, Pawnee and Iroquois maidens, Inca and Postclassic Mayan boys and girls, children of South India's tribal Lambadi)?
- Chopping off a finger for dead warriors or relatives (Dani of New Guinea, Crow and other American Plains Indians)?

- Burning one's house and all other possessions for a family member drowned, crushed by a tree, or killed by a tiger (Nāga tribes of Assam)?
- Knocking out one's own teeth (Australian aboriginals)?
- Making elaborate but evanescent sand designs (Navajo, tribes of Central Australia)?
- Giving up one's life to keep Fridays (Muslims) or Saturdays (Jews) or Sundays (Christians) holy?

Try to come up with an adaptive logic that generates a unitary explanation for all of these phenomena, or for just stopping whatever one is doing to murmur often incomprehensible words while gesticulating several times a day. As Bill Gates aptly surmised, "Just in terms of allocation of time resources, religion is not very efficient. There's a lot more I could be doing on a Sunday morning" (cited in Keillor, 1999).

Evolution cannot account for religion simply as an adaptation for some ancestral task that is "hardwired" into us. There is no gene for the complex of beliefs and behaviors that make up religion, any more than there is a gene for science; nor is there likely any genetic complex with law-like or systematic qualities that is responsible for most religious belief or behavior. It is rash and very likely wrong to infer that because nearly every historically successful human society was religiously based (especially popular in sociobiology) nature selected a propensity for religion because ancestral tribes that believed themselves favored in battle by the gods were victorious over other tribes. For if one seriously considers the beliefs of people who think they are favored by the gods and how they behave as a result, then one has got a good chunk of human belief and behavior to cover.

ADAPTATIONIST THEORIES OF RELIGION

Adaptationist arguments usually attempt to offset the apparent functional disadvantages of religion with even greater functional advantages. Adaptationists study traits within specific ecological contexts and evaluate whether a current trait produces the highest reproductive success given the alternative strategies available. This has yet to be determined for any religious trait. Nor have researchers examined religions' ability to respond to the selective

pressures of diverse ecological contexts. In other words, to date, most of the adaptationist literature on religion is largely theoretical and offers only a few empirical tests (for exceptions see Sosis, 2000; Sosis & Bressler, 2003; Bering & Borklund, 2004).

Social Control

Behavioral ecologists have argued that evolution is a competitive process in which selection occurs at the individual, rather than the group, level (Dawkins & Krebs, 1978; cf. Barrett, Dunbar, & Lycett, 2001). From this vantage, selective pressures should favor deceptive strategies when individuals can exploit other group members for individual advantage. Thus, interactions between signalers and receivers should escalate in an evolutionary arms race in which signalers attempt to influence the behaviors of receivers to their own advantage, and receivers attempt to recognize deception and resist manipulation that is not in their best interests. The result of such escalation would be increasingly complex ritual behaviors as senders attempt to deceive receivers, and receivers seek to determine the truthfulness of senders' signals.

Cronk (1994) applied this reasoning to explore human moral systems cross-culturally. In contrast to previous work that emphasized how moral systems enhance cooperation within groups (Alexander, 1987), Cronk observed that despite the benefits of mutualism (a relationship between two species that benefits both), there are still conflicts of interests within groups. As a result of these conflicts, moral statements can be used to manipulate others to benefit the signalers at a cost to the receivers. Cronk argues that religion can be used by elites to maintain social control, noting that this claim is supported by the classic cross-cultural study by Swanson (1960), who found egalitarian societies to be more likely than egalitarian societies to believe in moralizing and punishing gods. Cronk follows Krebs and Dawkins (1984), who claimed that cooperative signals should be simple, whereas manipulative signals should be more elaborate, with greater repetition. Thus, religious communities concerned with conquest, control, and conversion should have more elaborate and repetitive displays than communities with little interest in "convincing any nongroup members of their correctness." But this hypothesis yet has to be reliably tested.

Costly Signaling Theory

Some researchers have observed that the hypothesized “arms race” between deceivers and receivers does not always occur. For example, when a direct link between signal and underlying condition exists, as between physical size and vocal signal frequency, deception is precluded (Johnstone, 1998). Zahavi (1975) argued that even in the absence of such direct physical linkage, it is possible to ensure signal reliability *if signals are differentially costly to produce*. In other words, signals expressing phenotypic condition can be honest if the costs to lower quality organisms of imitating the signals of higher quality organisms outweigh the benefits that can be achieved (Grafen, 1990).

Various researchers have proposed the application of costly signaling theory to religious ritual to explain how social cohesion is promoted by religion or, more generally, how nonkin groups manage to cooperate in order to compete with rival groups (Irons, 1996; Sosis & Alcorta, 2003; Bulbulia, 2004). These researchers view religion's ability to promote solidarity as its primary function but recognize that social bonding is not an end in itself; by increasing solidarity religion facilitates intra-group cooperation. Indeed, Irons (2001) argued that the primary adaptive benefit of religion is its ability to promote cooperation and overcome problems of collective action that humans have faced throughout their evolutionary history, including cooperative hunting, food sharing, defense, and warfare. When faced with the conditions of collective action, the incentive to claim falsely that one will cooperate is especially high, because individuals can achieve their greatest gains by refraining from cooperation when others cooperate. Although everyone may gain if all group members invest in the cooperative goal, attainment of such large-scale cooperation is often difficult to achieve without social mechanisms limiting the potential to free ride on the efforts of others. Therefore, whenever an individual can achieve net benefits from defection, the only credible signals of cooperative intentions are those that are “costly to fake”; otherwise, they can easily be imitated by free riders, who do not intend to invest in the cooperative pursuit.

The costly signaling theory of ritual posits that religious behaviors or rituals are costly-to-fake signals that advertise an individual's level of commitment to a religious group. Preferred

signalers are those who are highly committed to the goals and ideals of the group, which typically include ingroup altruism. Cooperation is facilitated because those who are uncommitted can be avoided as partners in collective action, because they will find it too expensive to pay the costs of religious behavior. In ethno-historical studies on 19th-century U.S. communes and economic field experiments on Israeli kibbutzim, Sosis and colleagues have demonstrated a positive association between participation in religious ritual and enhanced cooperation (Sosis & Bressler, 2003; Sosis & Ruffle, 2004); however, they have yet to examine how the high levels of cooperation observed within religious communities translate into individual fitness gains.

Ritual Healing Theory

McClenon (2002) offers an intriguing theory of the evolution of religion. He notes that ancestral primates undoubtedly used rudimentary rituals to alleviate social stress. Social grooming in nonhuman primates, as well as the ritualized hand gestures of hominoids and the chimpanzee “rain dance” described by Goodall (1986) all constitute such rituals. McClenon argues that hominins developed more complex rituals that produced therapeutic altered states of consciousness. He claims, citing Winkelman (1992), that shamanic healing “was present in all regions of the world at some time in their hunting and gathering past.” According to McClenon (2002), those who were most suggestible in our evolutionary past would have benefited most from shamanic healing ceremonies, resulting in lower morbidity and mortality rates. Accepting the efficacy of shamanistic healing would have been particularly valuable to birthing mothers, thus directly contributing to reproductive success. He concluded that suggestibility and hypnotizability confer adaptive advantages on those who possess these traits.

McClenon's theory (2002) integrates several critical features of religion and suggests a linkage between proximate neurophysiological mechanisms of religious ritual and evolutionary causation. First, it addresses what most believe to be the earliest form of religion, shamanism. Although Irons and Chagnon (2002) have shown how Yanomamo shamanistic religion and beliefs can be understood as costly signals of commitment, the costly signaling theory of religion does not account for why sha-

manistic religion should focus on healing. Indeed, the second important contribution of the ritual healing theory is that it accounts for why religion is universally associated with health and healing practices. There is an extensive literature showing a negative relationship between religious practice and belief, and morbidity and mortality rates (Hummer, Rogers, Narn, & Ellison, 1999; Levin, 1994; Matthews et al., 1998). The ritual healing theory of religion offers possible insights into this relationship.

The Symbolic Species

Deacon (1997) has proposed an alternative evolutionary theory of religion that situates the origins of human religious ritual in our unique social structure. Observing that humans are the only pair-bonded primate with significant paternal investment to live in large, multimale groups, he notes that the inherent difficulty of maintaining pair-bonds when females are in close proximity to other potential mates probably accounts for its rarity across species. Deacon further argues that the risk of cuckoldry is compounded by the human foraging ecology: Males cannot continually mate during periods of high female fertility, because male and female resource acquisition often occurs separately. Deacon proposes that symbolic culture arose in response to this dilemma so as to represent a social contract for which prior indexical communication (e.g., calls, display behaviors) was insufficient. Rituals allowed a shift from indexical signs that connect abstractions with objects to signs that connect two abstractions. Religious ritual achieves this by inducing new “gestalts” and binding abstractions through emotions. For example, marriage rituals link the abstraction of future behaviors regarding sexual fidelity to the community and are sanctified through emotional associations. Deacon—in line with Durkheim (1912/1995), Rappaport (1999), and Burkert (1996)—maintains that ritual is the foundation of the social contract and enables the extensive reciprocal relationships that make human life, as we know it, possible. Deacon’s hypothesis of hominid pair-bonding as the evolutionary driving force for religious ritual remains highly speculative, although broader research into how ritual can cement commitment in intersexual relationships is likely to have a promising in evolutionary psychology.

Ritual and Emotion

The work of Alcorta and Sosis (2005) focuses on religion as an adaptive complex intimately linked to the neural plasticity of hominids. These authors identify four traits of religion recurrent across cultures including (1) belief systems incorporating supernatural agents and counterintuitive concepts; (2) communal ritual, (3) separation of the sacred and the profane; and (4) adolescence as a preferred developmental period for religious transmission. They propose both ontogenetic and neurophysiological proximate mechanisms underlying religious beliefs and behaviors, arguing that the critical element differentiating religious from nonhuman ritual is the conditioned association of emotion and abstract symbols. Incorporation of music as a central component of human ritual is critical to this process, and to the evolution of both protosymbolic thought and human religious systems. These authors propose neurophysiological mechanisms involved in the emotional valencing of symbolic systems and argue that the brain plasticity of human adolescence constitutes an “experience-expectant” developmental period for ritual conditioning of sacred symbols. The emotional charging of beliefs regarding social relationships subsequently drives behavioral choices. Food and sleep deprivation, fear, physical ordeals, and drugs increase neurophysiological impacts in terms of memory, reward learning, and emotional charging of stimuli. Alcorta and Sosis maintain that religious ritual, and the emotionally valenced symbolic systems it engenders, evolved to extend communication and coordination of social relations across time and space.

Alcorta and Sosis (2005) argue that far from being an evolutionary by-product, religion represents a critical adaptive complex—the emotional charging of beliefs in ritual being one key component—that evolved in response to ecological challenges faced by early human populations. The still largely untested assumption is that individual fitness benefits resulted from both participation in ritual itself and the cooperative activities it enabled. The empathy and shared emotional charging experienced in rites of passage supposedly give valence the cognitive schemas associated with sacred things, such as counterintuitive supernatural beliefs.

In summary, adaptationist theories of religion, such as costly signaling of social commitment, ritual healing to alleviate social stress,

and symbolic and emotional bonding theories, help us to understand potentially important mechanisms for generating social cohesion in the evolutionary competition for survival. But despite claims that various functional accounts singly or collectively produce an evolutionary explanation of religion, at best they represent (still largely speculative and untested) compatibility arguments about the social benefits of accommodating the various bits and pieces of beliefs and behaviors that characteristically figure in religion, as well as in many other aspects of social life (hunting and gathering, agricultural and trade associations, political ideology and government, musical ensembles and sports teams, etc.). There is no account of how the characteristically supernatural worlds that manage people's existential dilemmas are actually produced and/or predictably structured.

Some Other Evolutionary Accounts: Sociobiology, Group Selection, and Memetics

Other evolutionary approaches to religion and culture include sociobiology (Harris, 1974; E. O. Wilson, 1978), group selection theory (Sober & Wilson, 1998; Boehm, 1999), and memetics (Dawkins, 1976; Dennett, 1997). Proposals from these alternative approaches are often "mind-blind" to the cognitive constraints on religious beliefs and practices, viewing religion and culture as bundles of functionally integrated, fitness-bearing traits: for example, packages of environment-induced rituals (the material infrastructure underlying ideational superstructure), machine-like patternings of collective norms (worldviews), or partnerships of invasive and authorless ideas (memeplexes).

Proponents of these alternatives do not deny that minds have causally "proximate" roles in generating religious behaviors—as they may in generating economic behaviors—or that cognition may form part of some "ultimate" explanation of religion. Nevertheless, a common claim is that a meaningful causal account of such behaviors requires initial focus on measurable relationships between putative fitness-motivating factors in religious behaviors and ostensible fitness consequences (Dennett, 1995, pp. 358–359; Sober & Wilson, 1998, pp. 182, 193; cf. Lumsden & Wilson, 1981): for example, between individuals needing protein in animal-poor environments and ritual human sacrifice (E. O. Wilson, 1978; Harris, 1974),

between ideas endeavoring to propagate themselves and proselytizing for altruism (Lynch, 1996; Blackmore, 1999), or between groups competing for survival and Judaism's alleged cultural and genetic separatism to create eugenically a master race of economic calculators (MacDonald, 1998; D. S. Wilson, 2002). These arguments are presented through selective use of anecdotal evidence rather than being reliably tested and demonstrated.

Thus, despite sociobiological claims to the canons of "scientific materialism," the causal account that is supposed to produce religious practices (e.g., Aztec cannibalistic sacrifice) from their ostensible material functions (e.g., compensating for lack of large game as sources of protein in Mesoamerica) are wholly mysterious (e.g., How does eating someone generate the idea or formation of a pyramid or priest?). Moreover, similar practices often arise or endure independently, or regardless of material need: For example, the African Azande said they just preferred the taste of human meat (Evans-Pritchard, 1960), and game was abundant for Mesoamerica's Lowland Maya, who also practiced human sacrifice (deLanda, 1566/1985; Atran, Lois, & Ucan Ek', 2004).

It is also notoriously difficult to establish measurable criteria by which whole cultures/societies or worldviews/memeplexes can have fitness consequences.⁵ Functional accounts are often synthetic abstractions, for example, a lone anthropologist's normative digest of some culture that in reality has no clear boundaries and no systematically identifiable structural functions. Indeed, most reported "norms" are too semantically open-ended to have specific contents, such as the Ten Commandments: Even members of the same church congregation fail to provide interpretations of the Ten Commandments that other congregation members consistently recognize as being interpretations of the Ten Commandments (Atran, 2001). There are no "replicating" or even definite or definable cultural units for natural selection and vertical (transgenerational) or horizontal (contemporaneous) transmission (e.g., memes can be anything, from a gender marker to a partial tune, cell phone, cooking recipe, political philosophy, etc.). These facts render implausible attempts to explain religions (or cultures with a religious element) as discrete or integrated functional systems (for reviews of specific arguments, see Atran, 2001, 2002, 2005; Atran & Norenzayan, 2004).⁶

In brief, religious sacrifice generally runs counter to calculations of immediate utility, such that future promises are not discounted in favor of present rewards. In some cases, sacrifice is extreme. Although such cases tend to be rare, they are often held by society as religiously ideal: for example, sacrificing one's own life or nearest kin. Researchers sometimes take such cases as *prima facie* evidence of "true" (nonkin) social altruism (Rappaport, 1999; Kuper, 1996), or group selection, wherein individual fitness decreases so that overall group fitness can increase (relative to the overall fitness of other, competing groups; Sober & Wilson, 1998; D. S. Wilson, 2002). But this may be an illusion.

A telling example is contemporary suicide terrorism (Atran 2003). Consider the "oath to *jihad*" taken by people who join *Harkat al-Ansar*, a Pakistani-based ally of Al-Qaeda, which affirms that by their sacrifice, enlistees help secure the future of their "family" of fictive kin: "Each [martyr] has a special place—among them are brothers, just as there are sons and those even more dear" (cited in Rhode & Chivers, 2002, p. A1). In the case of religiously inspired suicide terrorism, these sentiments are purposely manipulated by organizational leaders, guides, and trainers to the advantage of the manipulating elites rather than to the individual (much as the fast food or soft drink industries manipulate innate desires for naturally scarce commodities such as fatty foods and sugar to ends that reduce personal fitness but benefit the manipulating institution). No "group selection" is involved for the sake of the cultural "superorganism" (D. S. Wilson, 2002; cf. Kroeber, 1923/1963), like a bee for its hive, only cognitive and emotional manipulation of some individuals by others. In evolutionary terms, quest for status and dignity may represent proximate means to the ultimate end of gaining resources, but as with other proximate means (e.g., passionate love), they may become emotionally manipulated ends in themselves (Tooby & Cosmides, 1992).

RELIGION AS EVOLUTIONARY BY-PRODUCT

There are many different and even contrary explanations for why religion exists in terms of beneficial functions served. These include functions of social (bolstering group solidarity, group competition), economic (sustaining pub-

lic goods, surplus production), political (mass opiate, rebellion's stimulant), intellectual (e.g., explain mysteries, encourage credulity), health and well-being (increase life expectancy, accept death), and emotional (terrorizing, allaying anxiety) utility. Many of these functions have prevailed in one cultural context or another, yet all have also been true of cultural phenomena besides religion.

Such descriptions of religion often help to explain insightfully how and why given religious beliefs and practices help to provide competitive advantages over other sorts of ideologies and behaviors for cultural survival. Still, these accounts provide little explanatory insight into cognitive selection factors responsible for the ease of acquisition of religious concepts by children, or for the facility with which religious practices and beliefs are transmitted across individuals. They have little to say about which beliefs and practices—all things being equal—are most likely to recur in different cultures and most disposed to cultural variation and elaboration. None predicts the following cognitive peculiarities of religion:

- Why do *agent* concepts predominate in religion?
- Why are *supernatural-agent* concepts culturally universal?
- Why are *some* supernatural agent concepts *inherently better* candidates for cultural selection than others?
- Why is it necessary, and how it is possible, to *validate* belief in supernatural agent concepts that are logically and factually inscrutable?
- How is it possible to prevent people from deciding that the existing moral order is simply wrong or *arbitrary*, and from stealthily *defecting* from the social consensus through *deception*, thus fatally compromising social cohesion?

This argument does not imply that religious beliefs and practices cannot perform social functions, or that the successful performance of such functions does not contribute to the survival and spread of religious traditions. Indeed, there is substantial evidence that religious beliefs and practices often alleviate potentially dysfunctional stress and anxiety (Ben-Amos, 1994; Worthington, Kurusu, McCullough, & Sandage, 1996), and maintain social cohesion in the face of real or perceived conflict (Allport, 1956; Pyszczynski, Greenberg, & Solomon,

1999). It does imply that social functions are not phylogenetically responsible for the cognitive structure and cultural recurrence of religion.

The general idea is that religion is not an evolutionary adaptation *per se* but a recurring cultural by-product of the complex evolutionary landscape that sets cognitive, emotional and material conditions for ordinary human interactions (Kirkpatrick, 1999; Boyer, 2001; Atran, 2002; Pinker, 2004). Religion exploits ordinary cognitive processes to passionately display costly devotion to counterintuitive worlds governed by supernatural agents. The conceptual foundations of religion are intuitively given by task-specific, panhuman cognitive domains, including folkmechanics, folkbiology, and folkpsychology. Core religious beliefs minimally violate ordinary notions about how the world is, with all of its inescapable problems, thus enabling people to imagine minimally impossible supernatural worlds that solve existential problems, including death and deception.

Supernatural agents, such as ghosts, the Abrahamic Deity, and the Devil, are much like human agents psychologically (belief, desire, promise, inference, decision, emotion) and biologically (sight, hearing, feel, taste, smell, coordination) but lack material substance and some associated physical constraints. These imaginary worlds are close enough to factual, everyday worlds to be not only perceptually compelling and conceptually tractable but also surprising enough to capture attention, prime memory, and “contagiously” spread from mind to mind. This gives beliefs in the supernatural and associated behaviors an advantage in the competition for cultural survival.

Supernatural beliefs and behaviors gain coherence and further advantage when they focus on the management of people's existential anxieties. Religion has endured in nearly all cultures and most individuals because humans are faced with problems they cannot solve. As people routinely interact, they naturally tend to exploit various mundane cognitive faculties in special ways to solve an array of inescapable, existential problems that have no apparent worldly solution. Consider death. Because we have cognitive abilities to travel in time and track memory, we are automatically aware of death everywhere. Physical death is something that organisms have evolved to avoid. People seek some kind of a long-term solution to this

looming prospect, but there is none. That's the “tragedy of cognition.” Lucretius and Epicurus thought they could solve this through reason. They said, “Look, what does it matter? We weren't alive for infinite generations before we were born. It doesn't bother us. Why should we be worried about the infinite generations that will come after us?” Nobody bought that line of reasoning, because anyone who is alive has got something to lose (cf. Kahneman & Tversky, 1979).

Another existential problem is deception. Recent experiments in developmental psychology show that children are aware of deception at least by age 3 (and perhaps as early as 15 months; K. Onishi & Baillargeon, 2005). If you have rocks and plants and bodies of water before you and say, “Oh, there's no piece of iron there,” “That's not wet,” or “That's not really a tree,” someone can come along and say, “Look, you're nuts; I can touch it; I can show you it's a piece of iron.” For commonsense physical events, we have ways of verifying what is real or not. For moral judgments, we have nothing comparable. If someone says, “Oh, he should be a beggar and he should be a king,” or “Murder is bad and capital punishment is good,” what is there in the world to prove this so? If nothing is sure, how will people ever get on with one another, especially nonkin? How can they build societies and come to trust one another, so they will not defect? One solution involves inventing a minimally counterintuitive world governed by deities, who watch over people to make sure that there will be no defectors or shirkers.

All of this is not to say that *the* function of religion is to promise resolution of all outstanding existential anxieties, any more than *the* function of religion is to neutralize moral relativity and establish social order to give meaning to an otherwise arbitrary existence, to explain the unobservable origins of things, and so on. Religion has no evolutionary functions *per se*. Rather, existential anxieties and moral sentiments constitute—by virtue of evolution—ineluctable elements of the human condition, and the cognitive invention, cultural selection, and historical survival of religious beliefs are due in part to success in simultaneously accommodating these evolutionarily disparate elements. To be sure, there are evolutionarily adapted behaviors (e.g., costly signaling, ritual engagement) that contribute to the production and endurance of religious beliefs and behav-

iors, including those that carry likely fitness benefits for individuals (e.g., mental health and psychological well-being, cooperation and friendship) as they bond to form cohesive and competitive social groups. But religion is both psychologically much more and behaviorally much less than the product of naturally selected mechanisms that generate intragroup cooperation for intergroup competition.

THE SUPERNATURAL AGENT: HAIR-TRIGGER FOLKPSYCHOLOGY

Religions invariably center on supernatural *agent* concepts, such as gods, goblins, angels, ancestor spirits, and jinns. Granted, nondeistic “theologies” such as Buddhism and Taoism doctrinally eschew personifying the supernatural or animating nature with supernatural causes. Nevertheless, common folk who espouse these faiths routinely entertain belief in an array of gods and spirits that behave counterintuitively in ways that are inscrutable to factual or logical reasoning.⁷ Even Buddhist monks ritually ward off malevolent deities by invoking benevolent ones, and conceive altered states of nature as awesome.⁸

Mundane agent concepts are central players in what cognitive and developmental psychologists refer to as “folkpsychology” and the “theory of mind.” A reasonable speculation is that hair-trigger agency evolved so that humans respond “automatically” under conditions of uncertainty to potential threats (and opportunities) by intelligent predators (and protectors). From this evolutionary perspective, agency is a sort of “innate releasing mechanism” (Tinbergen, 1951) whose proper evolutionary domain encompasses animate objects, but which inadvertently extends to moving dots on computer screens, voices in the wind, faces in the clouds, and virtually any complex design or uncertain circumstance of unknown origin (Guthrie, 1993; cf. Hume, 1757/1956).

A number of experiments show that children and adults spontaneously interpret the contingent movements of dots and geometrical forms on a screen as interacting agents with distinct goals and internal motivations for reaching those goals (Heider & Simmel, 1944; Premack & Premack, 1995; P. Bloom & Veres, 1999; Csibra, Gergely, Biró, Koós, & Brockbank, 1999). Such a biologically prepared, or “modu-

lar,” processing program would provide a rapid and economical reaction to a wide—but not unlimited—range of stimuli that would have been statistically associated with the presence of agents in ancestral environments. Mistakes, or “false positives,” would usually carry little cost, whereas a true response could provide the margin of survival (Seligman, 1971; Geary & Huffman, 2002).

Our brains may be trip-wired to spot lurkers (and to seek protectors) when conditions of uncertainty prevail (when startled, at night, in unfamiliar places, during a sudden catastrophe, and in the face of solitude, illness, prospects of death, etc.). Plausibly, the most dangerous and deceptive predator for the genus *Homo* since the Late Pleistocene has been *Homo* itself, which may have engaged in a spiraling behavioral and cognitive arms race of individual and group conflicts (Alexander, 1989). Given the constant menace of enemies within and without, concealment, deception, and the ability to generate and recognize false beliefs in others would favor survival. In potentially dangerous or uncertain circumstances, it would be best to anticipate and fear the worst of all likely possibilities: presence of a deviously intelligent predator.

From an evolutionary perspective, argues Stewart Guthrie (1993), it is better to be safe than sorry regarding the detection of agency under conditions of uncertainty. This cognitive proclivity would favor emergence of malevolent deities in all cultures, just as a countervailing Darwinian propensity to attach to protective caregivers would favor apparition of benevolent deities. Thus, for the Carajá Indians of Central Brazil, intimidating or unsure regions of the local ecology are religiously avoided: “The earth and underworld are inhabited by supernaturals. . . . There are two kinds. Many are amiable and beautiful beings who have friendly relations with humans. . . . Others are ugly and dangerous monsters who cannot be placated. Their woods are avoided and nobody fishes in their pools” (Lipkind, 1940, p. 249). Similar descriptions of supernaturals appear in ethnographic reports throughout the Americas, Africa, Eurasia, and Oceania (Atran, 2002).

In addition, humans *conceptually create* information to mimic and manipulate conditions in ancestral environments that originally produced and triggered evolved cognitive and

emotional dispositions (Sperber, 1996). Humans habitually “fool” their own innate releasing programs, such as when people become sexually aroused by makeup (which artificially highlights sexually appealing characteristics), fabricated perfumes, or undulating lines drawn on paper or dots arranged on a computer screen, that is, pornographic pictures.⁹ Indeed, much of human culture—for better or worse—can be arguably attributed to focused stimulations and manipulations of our species’ innate proclivities. Such manipulations can serve cultural ends far removed from the ancestral adaptive tasks that originally gave rise to those cognitive and emotional faculties triggered, although manipulations for religion often centrally involve the collective engagement of existential desires (e.g., wanting security) and anxieties (e.g., fearing death).

Recently, a number of devout American Catholics eyed the image of Mother Teresa in a cinnamon bun sold at a shop in Tennessee. Latinos in Houston prayed before a vision of the Virgin of Guadalupe, whereas Anglos saw only the dried remnants of melted ice cream on a pavement. Cuban exiles in Miami spotted the Virgin in windows, curtains, and television afterimages as long as there was hope of keeping young Elian Gonzalez from returning to godless Cuba. And on the day of the World Trade Center bombing, newspapers showed photos of smoke billowing from one of the towers that “seems to bring into focus the face of the Evil One, complete with beard and horns and malignant expression, symbolizing to many the hideous nature of the deed that wreaked horror and terror upon an unsuspecting city” (“Be-deviling: Did Satan Rear His Ugly Face?,” *Philadelphia Daily News*, September 14, 2001). In all these cases, there is culturally conditioned emotional priming in anticipation of agency. This priming, in turn, amplifies the information value of otherwise doubtful, poor, and fragmentary agency-relevant stimuli. This enables the stimuli (e.g., cloud formations, pastry, ice-cream conformations) to achieve the minimal threshold for triggering hyperactive facial recognition and body-movement recognition schemas that humans possess.

In summary, supernatural agents are readily conjured up, perhaps because natural selection has trip-wired cognitive schemas for agency detection in the face of uncertainty. Uncertainty is omnipresent; so, too, is a hair-trigger agency-

detection mechanism that readily promotes supernatural interpretation and is susceptible to various forms of cultural manipulation. Cultural manipulation of this modular mechanism and priming facilitate and direct the process. Because the phenomena created readily activate intuitively given modular processes, they are more likely to survive transmission from mind to mind under a wide range of different environments and learning conditions than entities and information that are harder to process (Atran & Sperber, 1991; Boyer, 2000). As a result, they are more likely to become enduring aspects of human cultures, such as belief in the supernatural.

COUNTERINTUITIVE WORLDS

The supernatural occupies counterintuitive worlds that are not merely counterfactual in the sense of physically implausible or nonexistent. Rather, the supernatural literally lacks truth conditions. A counterintuitive notion can take the surface form of a proposition (e.g., “Omnipotence [i.e., God] is insubstantial”), but the structure of human semantics is such that no specific meaning can be given to the expression, and no specific inferences generated from it (or, equivalently, any and all meanings and inferences can be attached to it). The meanings and inferences associated with the subject (omnipotence = physical power) of a counterintuitive expression contradict those associated with the predicate (insubstantial = lack of physical substance), as in the expressions “The bachelor is married” or “The deceased is alive.”

Aristotle (1963) was the first to point out in his *Categories* that such counterintuitive expressions cannot even be judged false, because no set of truth conditions could ever be definitely associated with them. He gave the example of “two-footed knowledge.” According to Aristotle, “two-footed” could be sensibly (truly or falsely) applied to all animals, but not to any sort of knowledge, because knowledge falls under the ontological category of nonsubstantial things, whereas being two-footed falls under the altogether distinct ontological category of substantial things. Trying to put together things from different ontological categories produces a “category mistake.”¹⁰ Cognitive and developmental psychologists ex-

perimentally have shown that children across cultures do not violate such categorical constraints on language learning when attempting to learn the meaning of words (Keil, 1979; Walker, 1992).

All the world's cultures have attention-arresting religious myths because they are counterintuitive in this technical sense. Still, people in all cultures also recognize that such beliefs are counterintuitive, whether or not they are religious believers (Atran, 1996). In our society, for example, Catholics and non-Catholics alike are unquestionably aware of the difference between Christ's body and ordinary wafers, or between Christ's blood and ordinary wine. Likewise, the Native American Cowlitz are well aware of the difference between the deity Coyote and everyday coyotes, or between Old Man Wild Cherry Bark and ordinary wild cherry bark (Jacobs, 1934, pp. 126–133).

Religious beliefs are counterintuitive because they violate what studies in cognitive anthropology and developmental psychology indicate are universal expectations about the world's everyday structure, including such basic categories of "intuitive ontology" (i.e., the ordinary ontology of the everyday world that is built into the language learner's semantic system) as person, animal, plant, and substance (Atran, 1989). They are generally inconsistent with fact-based knowledge, though not randomly so. Beliefs about invisible creatures who transform themselves at will or perceive events that are distant in time or space flatly contradict factual assumptions about physical, biological, and psychological phenomena (Atran & Sperber, 1991). But apart from these few extraordinary and surprising features, such beings remain unsurprising and ordinary in terms of their beliefs, desires, reasonings, and behaviors. Consequently, these remarkable but tractable beliefs more likely will be retained and transmitted in a population than random departures from common sense, thus becoming part of the group's culture. Insofar as category violations shake basic notions of ontology they are attention-arresting, hence memorable; but only if the resultant impossible worlds remain bridged to the everyday world can information about them be readily be stored, evoked, and transmitted.

As a result, religious concepts need little in the way of overt cultural representation or instruction to be learned and transmitted. A few

fragmentary narrative descriptions or episodes suffice to mobilize an enormously rich network of implicit background beliefs (Boyer, 1994, 2001). For instance, if God is explicitly described as being jealous and able to move mountains, He is therefore implicitly known to have other emotions, such as anger and joy, and other powers, such as the ability to see and touch mountains, or to lift and see most anything smaller than a mountain, such as a person, pot, pig, or pea.

Invocation of supernatural agents implicates two cognitive aspects of religious belief: (1) activation of naturally selected conceptual modules, and (2) failed assignment to universal categories of ordinary ontology. Conceptual modules are activated by stimuli that fall into a few intuitive knowledge domains, including folkmechanics (inert object boundaries and movements), folkbiology (species configurations and relationships), and folkpsychology (interactive and goal-directed behavior). Ordinary ontological categories are generated by further, more specific activation of conceptual modules. Among the universal categories of ordinary ontology are *person, animal, plant, substance*.¹¹

To give an example, sudden movement of an object stirred by the wind may trigger the agent-detection system that operates over the domain of folkpsychology, and a ghost invoked to interpret this possibly purposeful event. In normal circumstances, a sudden movement of wind might activate cognitive processing for agents, but would soon deactivate upon further analysis ("it's only the wind"). But in the case of (bodiless) supernatural agents, the object-boundary detectors (edge, contour, etc.) that operate over the domain of folkmechanics, and which are required to identify the agent, cannot be activated. The same cognitive conditions operate when supernatural beings and events, like ghosts or gods, are evoked in religious ceremonies, whether or not there is any actual triggering event (e.g., a sudden movement of unknown origin or other uncertain happening). In such cases, assignment to the person or animal category cannot be completed, because ghosts and gods have counterintuitive properties (e.g., movements and emotions without physical bodies). This results in a potentially endless, open-textured evocation of possible meanings and inferences to interpret the event; however, the process can be provisionally stopped, and the semantic content somewhat specified, in a

given context (e.g., a Sunday sermon that fixes interpretation of a Biblical passage on some particular community event in the preceding week).

Ordinary ontological categories always involve more specific processing over the folkmechanics domain (nonliving objects and events).

- Only substance involves further processing that is exclusive to folkmechanics.
- Plant involves additional processing over the folkbiological domain (every organism is assigned to one and only one folk species).
- Animal involves supplemental processing over the domains of folkbiology (every animal is assigned uniquely to a folk species) and folkpsychology (animal behavior is scrutinized as indicating predator or prey, and possibly friend or foe).
- Person involves more specific processing over the folkpsychological domain (human behavior is scrutinized as indicating friend or foe, and possibly predator or prey), and the folkbiological domain (essentialized group assignments, e.g., race and ethnicity).

The relationship between conceptual modules and ontological categories is represented as a matrix in Table 17.1. Changing the intuitive relationship expressed in any cell generates what Pascal Boyer (2000) calls a “minimal counterintuition.” For example, switching the cell (– folkpsychology, substance) to (+ folkpsychology, substance) yields a thinking talisman, whereas switching (+ folkpsychology, person) to (– folkpsychology, person) yields an unthinking zombie (cf. J. Barrett, 2000).

These are general, but not exclusive, conditions on supernatural beings and events. Inter-

vening perceptual, contextual or psychoschematic factors, however, can change the odds. Thus, certain natural substances—mountains, seas, clouds, sun, moon, planets—are associated with perceptions of great size or distance, and with conceptions of grandeur and continuous or recurring duration. They are, as Freud surmised, psychologically privileged objects for focusing the thoughts and emotions evoked by existential anxieties such as death and eternity. Violation of fundamental social norms also readily lends itself to religious interpretation (e.g., ritual incest, fratricide, status reversal).

Finally, supernatural agent concepts tend to be emotionally powerful because they trigger evolutionary survival templates. This also makes them attention arresting and memorable. For example, an all-knowing bloodthirsty deity is a better candidate for cultural survival than a do-nothing deity, however omniscient. In the next section, I address some of the cognitive processes that contribute to the cultural survival of supernatural beliefs.

CULTURAL SURVIVAL: MEMORY EXPERIMENTS WITH COUNTERINTUITIVE BELIEFS

Many factors are important in determining the extent to which ideas achieve a cultural level of distribution. Some are ecological, including the rate of prior exposure to an idea in a population, physical and social facilitators and barriers to communication and imitation, and institutional structures that reinforce or suppress an idea. One complex of psychological factors concerns the apparent sensitivity to religious ideas in young children. Research with American and European children indicates that

TABLE 17.1. Mundane Relations between Naturally Selected Conceptual Domains and Universal Categories of Ordinary Ontology.

Ontological categories	Conceptual domains and associated properties				
	Folkmechanics	Folkbiology		Folkpsychology	
	Inert	Vegetative	Animate	Psychophysical (e.g., hunger, thirst, etc.)	Epistemic (e.g., believe, know, etc.)
Person	+	+	+	+	+
Animal	+	+	+	+	–
Plant	+	+	–	–	–
Substance	+	–	–	–	–

Note. Changing the relation in any one cell (+ to –, or – to +) yields a minimal, supernatural counterintuition.

through grade 1 (age 6–7), most children think that God is present everywhere, can hear prayers and see everything, and is near when they feel troubled or happy. This lends credence to the Jesuit mantra: “Give me a child till the age of 7 and I’ll give you a Believer for life.” Sentiments about God’s pervasiveness in life seem to degrade with age unless institutionally supported, and God’s presence and guidance become associated more with danger and difficulties (Thun, 1963; Goldman, 1964; Tamminen, 1994).

Of all cognitive factors, however, mnemonic power may be the single most important one at any age (Sperber, 1996). In oral traditions that have characterized most human cultures throughout history, an idea that is not memorable cannot be transmitted and cannot achieve cultural success (Rubin, 1995). Moreover, even if two ideas pass a minimal test of memorability, a *more* memorable idea has a transmission advantage over a less memorable one (all else being equal). This advantage, even if small at the start, accumulates from generation to generation of transmission, leading to massive differences in cultural success at the end.

One of the earliest accounts of memorability and the transmission of counterintuitive cultural narratives was Bartlett’s (1932) classic study of “The War of the Ghosts.” Bartlett examined the ways British university students remembered, then transmitted a Native American folktale. Over successive retellings of the story, some culturally unfamiliar items or events were dropped. Perhaps Bartlett’s most striking finding was that the very notion of the ghosts—so central to the story—was gradually eliminated from the retellings, suggesting that counterintuitive elements are at a cognitive disadvantage. Other unfamiliar items were distorted, being replaced by more familiar items (e.g., a canoe replaced by a rowboat).

In recent years, though, growing theoretical and empirical work suggest that minimally counterintuitive concepts are cognitively optimal; that is, they enjoy a cognitive advantage in memory and transmission in communication. In one series of experiments, J. Barrett and Nyhoff (2001) asked participants to remember and to retell Native American folktales containing both natural and nonnatural events or objects. Content analysis showed that participants remembered 92% of minimally counterintuitive items but only 71% of intuitive items.¹² These results, contrary to the find-

ings in Bartlett’s classic experiments, seem to indicate that minimally counterintuitive beliefs are better recalled and transmitted than intuitive ones.

Importantly, the effect of counterintuitiveness on recall is not linear. Too many ontological violations render a concept too counterintuitive to be comprehensible and memorable. Boyer and Ramble (2001) demonstrated that concepts with too many violations were recalled less well than those that were minimally counterintuitive. These results could be observed immediately after exposure, as well as after a 3-month delay, in cultural samples as diverse as the Midwestern United States, France, Gabon, and Nepal. Consistent with the idea that this memory advantage is related to cultural success, a review of anthropological literature indicates that religious concepts with too many ontological violations are rather rare (Boyer, 1994).

Although suggestive, these studies leave several issues unresolved. For one: why do minimally counterintuitive concepts not occupy most of the narrative structure of religions, folktales, and myths? Even casual perusal of culturally successful materials, such as the Bible, Hindu *Veda*, or Maya *Popul Vuh*, suggests that counterintuitive concepts and occurrences are a minority. The Bible is a succession of mundane events—walking, eating, sleeping, dreaming, copulating, dying, marrying, fighting, and suffering storms and drought—interspersed with a few counterintuitive occurrences, such as miracles and appearances of supernatural agents (e.g., God, angels, and ghosts). One possible explanation for this is that counterintuitive ideas are transmitted in narrative structures. To the extent that narratives with too many counterintuitive elements are at a cognitive disadvantage, cognitive selection at the narrative level would favor minimally counterintuitive narrative structures.

In one study that tested this hypothesis, Norenzayan, Atran, Faulkner, and Schaller (2006) analyzed folktales possessing many of the counterintuitive aspects of religious stories. They examined (1) the cognitive structure of Grimm Brothers’ folktales, and (2) the relative cultural success of each tale. The hypothesized nonlinear relation between the frequency of counterintuitive elements and cultural success was confirmed (Figure 17.1). Minimally counterintuitive folktales (containing two to three supernatural events or objects) consti-

FIGURE 17.1. Frequency distribution of counterintuitive elements contained in samples of culturally successful and unsuccessful folktales.

tuted 76.5% of culturally successful sample, whereas stories with fewer counterintuitive elements (scores < 2), and with excessive numbers of counterintuitive elements (scores > 3) constituted only 30% and 33% of the culturally successful sample, respectively. Overall, minimal counterintuitiveness predicted cultural success of folktales accurately 75% of the time. Perceived memorability and ease of transmission, but not other features of the folktale (e.g., whether the tale contains a moral lesson, interest value to children), partly mediated the relationship between minimal counterintuitiveness and cultural success. Whereas results indicate that cultural success is a nonlinear (inverted U-shape) function of the number of counterintuitive elements, success was not predicted by unusual narrative elements that are otherwise intuitive.

If memorability is the critical variable that mediates the effect of minimal counterintuitiveness on cultural success, than minimally counterintuitive knowledge structures should enjoy superior memory in the long run. To test this hypothesis more directly in a related study, Norenzayan, Atran, and Hansen (2005; reported in Atran & Norenzayan, 2004) examined the short- and long-term memorability of knowledge structures that systematically varied in the proportion of coun-

terintuitive elements. Their methodology differed from prior studies by employing “basic level” concepts (e.g., thirsty door) that are cognitively privileged (Rosch, Mervis, Grey, Johnson, & Boyes-Braem, 1976), and most commonly found in supernatural narratives. Participants were not cued to expect unusual events or to transmit interesting stories to others. Instead, Rosche et al. used a standard memory paradigm to measure recall.

The study examined the memorability of intuitive (INT) and minimally counterintuitive (MCI) beliefs and belief sets over a period of a week. Two-word statements that represented INT and MCI items were generated. Each statement consisted of a concept and one property that modified it. INT statements were created with use of a property appropriate to the ontological category (e.g., closing door). MCI statements were created with the concept modified by a property transferred from *another* ontological category (e.g., thirsty door). This procedure explicitly operationalizes minimal counterintuitiveness as the transfer of a property associated with the core conceptual domains of folkphysics, folkbiology, folkpsychology, from an appropriate ontological category of person, animal, plant, substance, to an inappropriate one (Atran & Norenzayan, 2004). For example, a “thirsty door” transfers

a folkbiological property (thirst) from its proper category (animal) to an improper category (inert object/substance).

U.S. students rated these beliefs on degree of supernaturalness using a 6-point Likert scale, with MCI beliefs significantly more likely than INT beliefs to be associated with supernaturalness. Although no differences were found in immediate recall, after 1-week delay minimally counterintuitive knowledge structures led to superior recall relative to all intuitive or maximally counterintuitive structures,¹³ replicating the curvilinear function found in the folktale analysis. With Yukatek Maya speakers, minimally counterintuitive beliefs were again more resilient than intuitive ones. A follow-up study revealed no reliable differences between the Yukatek recall pattern after 1 week and after 3 months (Atran & Norenzayan, 2004), indicating a cultural stabilization of the recall pattern.

In brief, minimally counterintuitive beliefs, as long as they come in small proportions, help people remember and presumably transmit the intuitive statements. A small proportion of minimally counterintuitive beliefs give the story a mnemonic advantage over stories with no counterintuitive beliefs, or with far too many counterintuitive beliefs. This dual aspect of supernatural beliefs and belief sets—commonsensical and counterintuitive—renders them intuitively compelling yet fantastic, eminently recognizable but surprising. Such beliefs grab attention, activate intuition, and mobilize inference in ways that greatly facilitate their mnemonic retention, social transmission, cultural selection, and historical survival. When emotional valence is added, these relevant mysteries (Sperber, 1996) become irresistibly catchy (Heath & Sternberg, 2001).

MODES OF RELIGIOSITY: AN ANTHROPOLOGICAL APPROACH TO RELIGIOUS TRANSMISSION

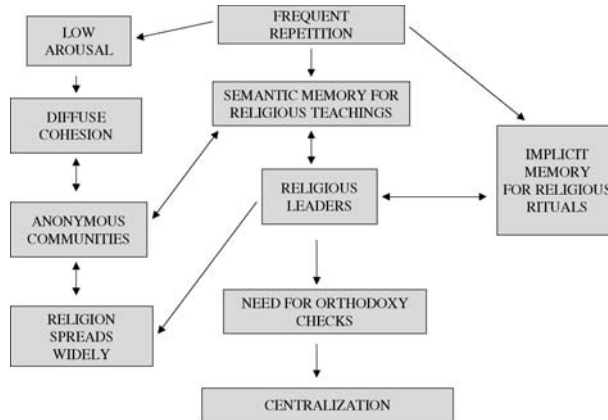

Religious traditions also involve the transmission of more complex and cross-culturally diverse concepts and practices, including ritual form (McCauley & Lawson, 2002), that present a further challenge to adherents' cognitive systems that go beyond mnemonic processing of intuitive and counterintuitive ideas. Why do religious beliefs become complex and challenging? And why is it so important to adherents that their own particular versions of "the truth" should transcend all others?

According to Harvey Whitehouse (2000, 2004), two factors greatly increase the chances that knowledge will be recalled. One is repetition. Repeating information increases the likelihood that it will be remembered. The other is arousal. Shocking or upsetting events are more likely to be recalled later than dull and unremarkable ones. But these two routes to remembering give rise to rather different kinds of recall. According to Whitehouse, religious traditions exploit these two kinds of memories in ways that have considerable consequences for the way religious concepts are formed and transmitted, and for the way religious traditions, as social institutions, are organized and spread.

In the doctrinal mode (Figure 17.2), religious practices tend to be frequently repeated and routine, such as daily prayer, weekly services, or annual celebrations. Frequent repetition supposedly builds an accurate memory routine for the ritual's abstract, schematic organization, or "script," such as the formulaic order of events in a Moslem prayer, Catholic mass or Jewish Passover. Participants customarily perform these scripted actions almost automatically but retain little long-term memory of the changing details and contents of the rites in question, such as who was actually present or what exactly was preached on a given occasion. Particular details and contents of scripted actions can vary substantially from one ritual performance to another. Yet the schematic sequence of events repeats with fairly high fidelity over time.

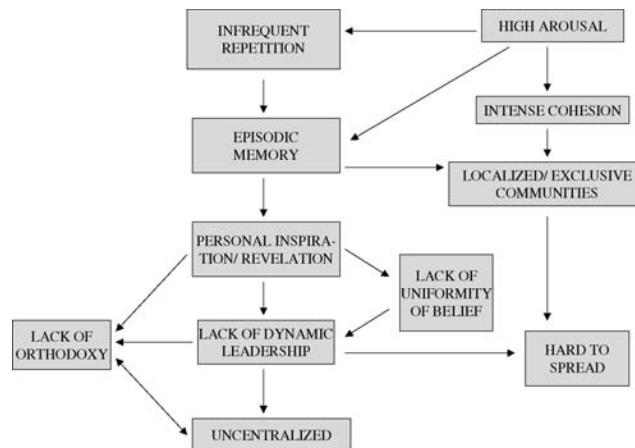

By tuning out the scripted routine, and forgetting changing details, participants are able to turn their attention to the "semantic" structure and "logical" implications of religious doctrine presented in exegesis, argumentation, and sermonizing. The repetitive routine is usually directed by a rigid social hierarchy. Routinization minimizes the risks of unintended innovations; hierarchization enhances monitoring, policing, and sanctioning of non-conformity. This normalizing design encourages indoctrination and preservation of orthodoxy. It also favors identification with masses of anonymous worshippers, which often promotes universalist and humanist notions of common fellowship.

In contrast to the "logocentric iconophobia" of the doctrinal mode (Whitehouse, 2000, p. 156), the imagistic mode (Figure 17.3) relies mainly on un verbalized, emotionally arousing

1. Frequent repetition activates semantic memory for religious teachings.
2. Semantic memory for religious teachings and the presence of religious leaders are mutually reinforcing features.
3. The presence of religious leaders implies a need for orthodoxy checks.
4. Frequent repetition leads to implicit memory for religious rituals.
5. Implicit memory for religious rituals enhances the survival potential of authoritative teachings stored in semantic memory.
6. The need for orthodoxy checks encourages religious centralization.
7. Semantic memory for religious teachings leads to anonymous religious communities.
8. The presence of religious leaders is conducive to the religion spreading widely.

FIGURE 17.2. Schematic presentation of the doctrinal mode of religious transmission.

1. Infrequent repetition and high arousal activate episodic memory.
2. Activation of episodic memory triggers spontaneous exegetical reflection.
3. SER leads to a diversity of religious representations.
4. SER and representational diversity inhibit dynamic leadership.
5. Lack of dynamic leadership, lack of centralization, and lack of orthodoxy are mutually reinforcing.
6. High arousal fosters intense cohesion.
7. Intense cohesion and episodic memory foster localized, exclusive communities.
8. Localized/exclusive communities and lack of dynamic leadership inhibit spread/dissemination.

FIGURE 17.3. Schematic presentation of the imagistic mode of religious transmission.

experiences and “episodic memory” of a spatiotemporally localized and autobiographical sort. The most sacred and revelatory rites in the imagistic mode are highly arousing, once-in-a-lifetime episodes.¹⁴ These are often physically excruciating and sensorially invasive: hideous masks and grotesquely painted dancers, horrifying cries and hoots, piercing whistles and pounding drums, overexposure to direct sunlight and heat or darkness and cold, extended sleep and food deprivation, anonymous pummeling and deep body laceration, and so forth. Possible examples of what Whitehouse (2000) calls “rites of terror” include initiations among Native American Cheyenne and Arapaho (Lowie, 1924), Navajo (Kluckhohn & Leighton, 1946/1974), Walbiri (Meggitt, 1965) and other aboriginals of the Central Australian Desert (Spencer & Gillen, 1904), Mountain Ok Baktaman (Barth, 1975) and Ilahita Arapesh of Highland Papua New Guinea (Tuzin, 1982), and Ituri Forest Pygmies in the African Congo (Turnbull, 1962). Although Whitehouse avoids equating the doctrinal, or “digital,” mode with large-scale Western religions or literacy, and the imagistic, or “analogic,” mode with small-scale tribal religions and cults, he argues that imagistic rituals are historically primary, dating at least to Upper Paleolithic cave art (see M. Turner, 1996).¹⁵

METAREPRESENTING COUNTERINTUITIVE WORLDS: A THEORY-OF-MIND EXPERIMENT

If counterintuitive beliefs arise by violating innately given expectations about how the world is built, how can we possibly bypass our own hardwiring to form counterintuitive religious beliefs? The answer is that we do not entirely bypass commonsense understanding, but we conceptually parasitize it to transcend it. This occurs through the cognitive process of metarepresentation.

Humans have a metarepresentational ability to form representations of representations. This allows people to understand a drawing or picture of someone or something as a drawing or picture, and not as the real thing. It lets us imagine fiction and gives us an ability to think about being in different situations and to decide which options are best for the purposes at hand, *without our having to actually live through (or die in) the situations we imagine*. It affords us the capacity to *model the world in*

different ways and to conscientiously change the world by entertaining new models that we invent, evaluate, and implement. It enables us to become aware of our experienced past and imagined future as past or future events distinct from the present we represent to ourselves, and so permits us to reflect on our own existence. It allows people to comprehend and interact with one another’s minds.

Metarepresentation also lets people retain half-understood ideas; children come to terms with the world in similar ways when they hear a new word. By embedding half-baked (quasi-propositional) ideas in other factual and commonsense beliefs, these ideas can simmer through personal and cultural belief systems and change them (Sperber, 1985; Atran & Sperber, 1991). A half-understood word or idea is initially retained metarepresentationally, as standing in for other ideas we already have in mind. Supernatural ideas always remain metarepresentational.

After Dennett (1978), most researchers in folkpsychology, or “theory of mind,” maintain that attribution of mental states, such as belief and desire, to other persons requires metarepresentational reasoning about false beliefs. Not before the child can understand that other people’s beliefs are *only* representations—and not just recordings of the way things are—can he or she entertain and assess other people’s representations as veridical or fictional, truly informative or deceptive, exact or exaggerated, or worth changing one’s own mind for or ignoring. Only then can the child appreciate that God thinks differently from most people, in that only God’s beliefs are always true.

In one of the few studies to replicate findings on “theory of mind” in a small-scale society (cf. Avis & Harris, 1991), Knight, Sousa, Barrett, and Atran (2004) showed 48 Yukatek-speaking children (26 boys, 22 girls) a tortilla container and told them, “Usually tortillas are inside this box, but I ate them and put these shorts inside.” They asked each child in random order what a person, God, the sun (*k’in*), principal forest spirits (*yumil k’ax’ob’*, “Masters of the Forest”), and other minor spirits (*chiichi’*) would think was in the box. As with American children (L. Barrett et al., 2001), the youngest Yukatek (age 4 years) overwhelmingly attribute true beliefs to both God and people in equal measure. After age 5, the children attribute mostly false beliefs to people but continue to attribute mostly true beliefs to

God. Thus, 33% of the 4-year-olds said that people would think tortillas were in the container, versus 77% of 7-year-olds. In contrast, no significant correlation was detected between answers for God and age.

Collapsing over ages, Yukatek children attribute true beliefs according to a hierarchy of human and divine minds, one in which humans and minor spirits are seen as easier to deceive. Mental states of humans were perceived as different from those of God, and those of Masters of the Forest and the Sun god. God is seen as all-knowing, and local religious entities fall somewhere in the middle (Figure 17.4). Lowland Maya believe God and forest spirits to be powerful, knowledgeable agents that punish people who overexploit forest species. For adults, such beliefs have measurable behavioral consequences for biodiversity, forest sustainability, and so forth (Atran et al., 2002). From an early age, people may reliably attribute to supernaturals cognitive properties that are *different* from those of their parents and other people.

In summary, metarepresentational abilities, which are intimately bound to fully developed cognitions of agency and intention, also allow
